ELECTRIC SUPPLY METERS.

No part of the material and plant used for the production and distribution of electric light has developed so slowly as the meter. Nearly as much mechanical ingenuity, and skill of a far higher order than has been expended on arc lamps, have been devoted to the design and perfecting of this necessary piece of apparatus. Before even a tolerable meter had been made, the efficiency of dynamos was well into the nineties. Glow lamps of a satisfactory quality had come into common use before any instrument was ready to record the current or the energy consumed by them. The construction of meters is, of course, a branch of mechanical work so different from dynamo building that there was no inducement for the larger manufacturing firms to add a meter department to their works. But it is singular that none of the well-known makers of electrical measuring instruments have successfully placed a meter on the market. Two exceptions are to be found among dynamo builders—the THOMSON-HOUSTON COMPANY and Messrs. FERRANTI and Co. are known for their meters as well as for their dynamos. Many names, such as ARON, FRAGER and SHALLENBERGER, are known to the electrical world only as inventors of meters. The time has not yet come for an exhaustive discussion of this subject, and only two Papers, so far as we remember, have been read, one by Prof. FORBES before the Society of Arts nearly five years ago, and one by Mr. WORDINGHAM before a students' meeting of the Institution of Civil Engineers.

The first meter was, we believe, that of Mr. J. T. SPRAGUE, patented November 22, 1878. This was a coulomb-meter for electro-plating work, and consisted of two copper plates, "supported by spiral springs, or in any other equivalent manner which will permit them to descend and rise according to their relative weights." A reversing commutator, ratchet wheels, and counting train were provided. Less than two years later Mr. EDISON patented almost precisely the same thing, with a balance arm instead of springs; but this was soon abandoned for his simple but unsatisfactory voltameter which lingers yet. The accelerated pendulum meter, one of the first practical instruments, was the invention of Profs. AYRTON and PERRY, who,

Digitized by Google

if the Chinese failed to invent it in the year *n* B.C., were as usual the first. Too early, however, for once were the early birds, for the early worm had not arrived. But only a few months before they allowed their patent to drop, Dr. ARON re-invented the pendulum meter, and added the differential train, which had been designed but not patented by the first inventors. The Aron meter, though made with insufficient care at first, served a useful purpose for several years, while other meters were being perfected. The principle of the pendulum meter has been carried to the highest refinement by Mr. EDMONDSON, and both he and the late Mr. RECKENZAUN have obviated the necessity for periodical winding by automatic electrical driving. It remains to be seen whether the additional mechanism, the liability to stop working, and the consumption of energy entailed by this improvement will enable the pendulum meter to keep its place among other competitors. The motor meter has perhaps received more attention than any other, and while the Thomson-Houston, Shallenberger, and Brillié meters have each been evolved on separate lines, the principle adopted by FAURE in February, 1882, has been elaborated by FERRANTI, HOOKHAM, and PERRY, each laying stress on a different point, and each attaining very high merit. The principle first proposed by J. E. H. GORDON—namely, a galvanometer with a snail cam, and an arm actuated by clockwork at intervals to strike the cam, and record the length of all its journeys—has been developed by CAUDRAY, FRAGER, Lord KELVIN, RICHARD, and others. But the complication and delicacy of the mechanism is so great that these meters must present very marked advantages if they are to compete with the simple disc or bell immersed in mercury, or the paddle driven by the mercury itself, rotating through the interaction of a radial current and an axial magnetic field. Apologising for, or defending the complication of, a delicate and complicated machine, a well-known engineer once observed that a watch is both delicate and complicated, but is none the less serviceable.

Most meters aim only at recording coulombs or ampere-hours. The constancy of the volts is assumed. Others measure the whole energy. An instrument with a shunt coil and with no iron core can of course measure the watts, but it is only in exceptional cases that the consumer wants to measure the energy. He generally wants candle-power, is charged for energy, but really buys current. A meter that took the sixth or seventh power of the volts into account would give an approximation to the candle-hours.

The essentials of a meter are accuracy, durability, low cost of maintenance, and low first cost. Accuracy must not only be a matter of laboratory testing, but the meter must stand packing, carriage, and erection. The older Aron meters worked fairly well when once at work, but the constants had, at great inconvenience, to be re-determined after the meters were fixed in place. The relative effect of errors in motor meters on small load before the constant is reached, and of full load errors, the effect of the correction introduced by Mr. EDMONDSON of what may be called the $2ab + b^2$, and the importance of both external and of C^2R temperature errors, might be discussed at great length. They are of vastly greater practical importance than problems about alternate currents in conductors having self-induction and capacity and the like. They bide their time; they will some day receive attention. Durability, of course, can only be estimated after several years' work, though the number of working parts, their speed, and their action, can be considered by inspection of the mechanism. The cost separates itself into two parts, the first cost forming part of the capital expenditure of the company, but one that is certain to earn a steady revenue; and the maintenance, which includes winding up, where clock meters are used, and the consumption of current, where shunt circuits are employed, either for driving the mechanism or for exciting electro-magnets. An elaborate discussion might be started on the price at which the shunt current should be debited in the company's accounts. Is it, for example, part of the current sent out to the consumer and chargeable to the total cost of production, or to "sheer" cost, or merely to cost of fuel? Engineers who will wrangle over the question of charging coal shovels to plant or to consumable stores, neglect this shunt current altogether. It has been pointed out by Mr. SWINBURNE that at 2d. per unit every watt lost in a shunt instrument is equal to the interest on £1 at 7 per cent., and that the saving of 10 watts therefore makes an instrument £10 cheaper. When meters are being sold at £6 or £7 each, this question must be seriously considered. There are in London alone, excluding the City, according to the last Board of Trade accounts, some £45,680 worth of meters. This is no less than one twelfth of the value of the "machinery and plant" at the stations, which amounts to £545,062. It is not fair to the consumers to say—it matters not whether meters cost £5 or £10, the cost is amply covered by rentals, for in many cases, especially in offices, the rental is a very perceptible part of the cost of lighting, and this is brought home to the consumer when he sees the charge in all its simplicity in the bill for the summer quarter. Were meters cheaper, rentals could be reduced without affecting the present rate of profit on capital outlay. Meters, then, form no inconsiderable part of the plant of a supply company, and the accuracy of the meters of course has a direct effect upon the revenue. Nor can the errors of meters be expected to cancel each other out, for a cautious consumer here and there will have his meter tested, especially if he has reason to think that it is erring in favour of the company. But of the meters which err in favour of the consumer less will be heard. We hope that the subject will attract more interest than hitherto. So great ingenuity has been spent on the designs, and such excellent results have been obtained, that the study of the construction of modern meters will amply repay the trouble spent on it.

OBITUARY.

SIR GEORGE ELLIOT.

We regret to announce the death, on Saturday afternoon last, of Sir George Elliot, Bart., well known in the electrical world on account of his early connection with submarine telegraphy.

Sir George Elliot was a typical Englishman. Born at Gateshead in 1815, and beginning life, as he often proudly boasted, at the bottom of a coal-pit, he worked through every stage of the industry with which his name is so widely connected. He early succeeded in creating for himself a fortune, which enabled him to take the place and exercise the influence belonging to energy of character, and shrewd, practical intelligence. In 1849 he acquired the business of Messrs. Kuper and Co., wire-rope makers, from the assignees of the firm, paying off their liabilities in full, and giving a handsome sum to Messrs. Kuper for the reversion. In this business he invited Mr., afterwards Sir, R. A. Glass to become a partner, and that gentleman in 1852 first adapted the principle of wire-covering for submarine cables which, successfully protecting them from the perils of the deep, had its share in the development of submarine cable industry to its present enormous proportions. The story of the laying of the Atlantic cable is well-known. After the failure of the cable which had been successfully laid in 1858, the Company were, from 1858 to 1864, engaged in raising new capital, and scientific men were making improvements in the form of cable and in

Digitized by Google

the apparatus for submerging it. Then the Telegraph Construction and Maintenance Company was formed, with Sir John Pender as Chairman, and absorbed the firm of Glass and Elliot and the Gutta Percha Company, and an entirely new cable, much thicker and more costly than the former one, was manufactured. The 2,300 miles, weighing more than 4,000 tons, of which this cable consisted, was shipped in 1865 on board the "Great Eastern," and when over 1,000 miles had been paid out the cable snapped by overstraining, and the end sank to the bottom. A new cable was constructed with a sufficient addition of the 1865 cable to repair the disaster of that year; and in 1866 both this new cable was laid and the lost cable of 1865 recovered and completed. Upon this occasion Mr. Glass received the honour of Knighthood. The firm subsequently became, and is now known as, Elliot and Co., wire rope makers, of Great George-street, Westminster; Cardiff and Durham. Sir George Elliot fought several severe political contests and represented South Durham in Parliament for many years, receiving his Baronetcy from Mr. Disraeli in 1874. At the time of his death he was Chairman of the Telegraph Construction and Maintenance Company and a Director of the Metropolitan Electric Supply Company.

THE HOOKHAM METER.

Since the invention in 1887 of a meter with an armature on a horizontal shaft, the armature being composed of a number of segments or windings, and the field-magnets between which it revolved being furnished with radial grooves to enable it to dipped was on the point of being splashed out of its trough. We only recall these defects in order to make a clear distinction between the present meter and the early instrument which it so little resembles.

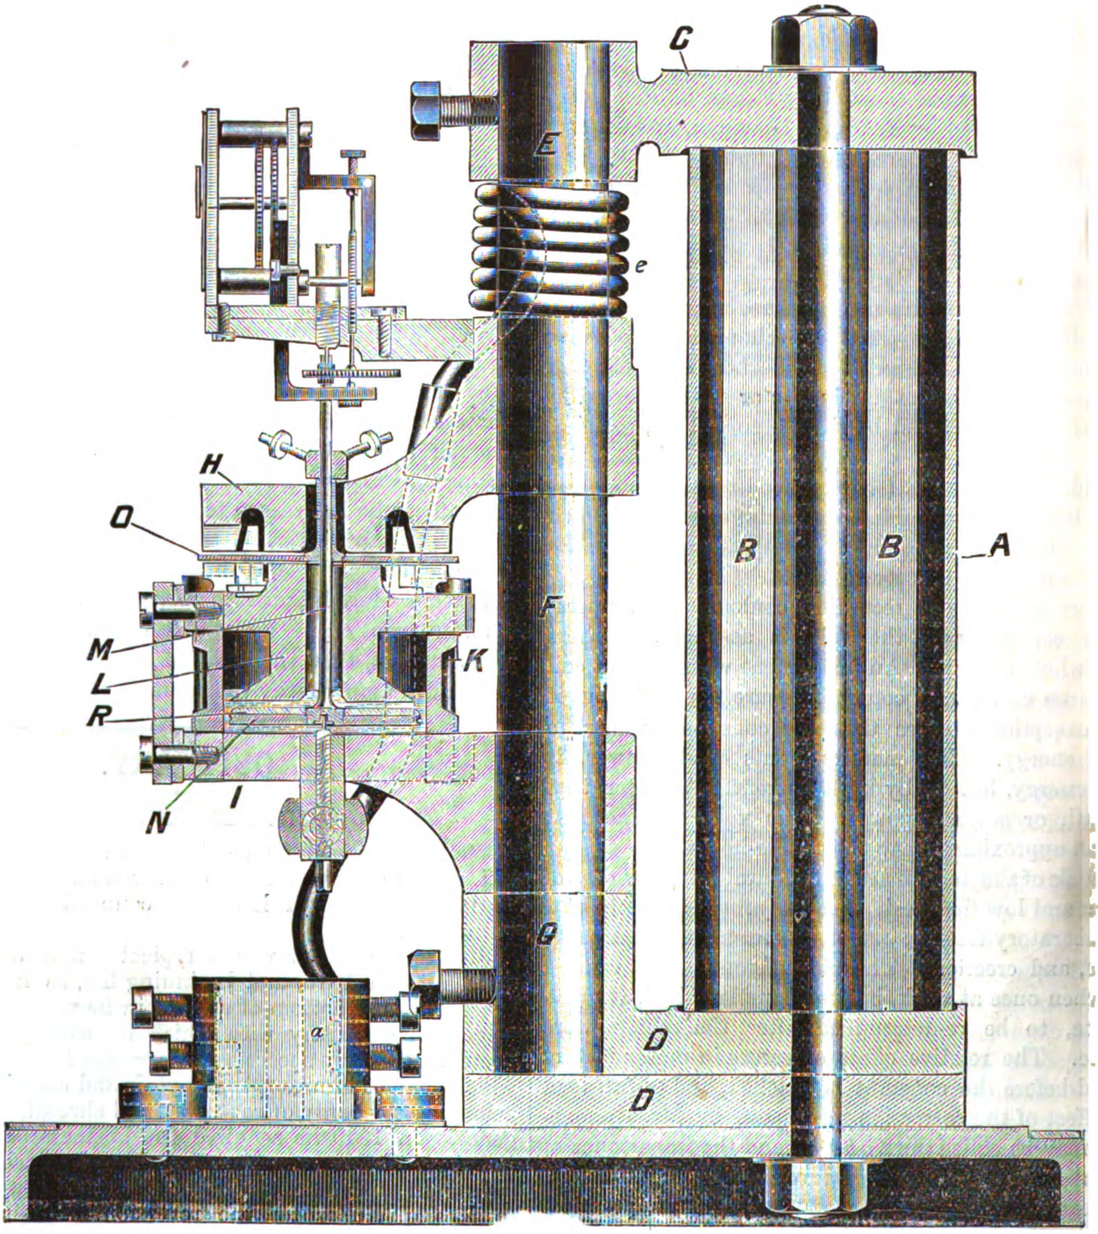

FIG. 1.

act as a magnetic brake, Mr. Hookham has gradually evolved a singularly interesting and valuable instrument. Most meters have been presented to the public in an immature condition, and the early Hookham meter not being an exception, we would call attention to the totally different pattern of the present instrument. The excessive surface friction affected the starting current, and if we remember rightly, at full load, the mercury in which the edge of the armature

The accompanying engravings represent a section and general view of a 50 ampere meter. A brass tube, A, Fig. encloses a number of steel bar magnets, B B. These are firm clamped between the cast-iron caps, C and D. The pilla E F G, is composed of three parts; E and G are wrought ir and the middle part, F, is of brass. Two pole pieces, H and are carried by the parts E and G. The flat upper surface of the pole piece, I, forms the bottom of a mercury cup. A coppe

ring, K, nickel faced on its inner surface, is held against the pole piece, I, by the iron cover, L. This cover is of such a shape that a large recess is afforded, somewhat on the unspillable ink-bottle principle, allowing space for the mercury in case the meter is tilted on one side, or even inverted, and preventing its escape through the central hole This cover spreading out at its foot reduces the magnetic reluctance of the air gap and acts as a pole piece. The armature, N, is a copper disc mounted on a vertical spindle ; it is faced on its

meter of Faure, nothing but the fluid friction of the mercury retarded the armature; but this friction does not follow the same law at high speeds as at low, and is so small that the armature would revolve at an extremely high speed, entailing considerable wear and tear and a longer train of wheels.

As in Mr. Hookham's first meter, a magnetic brake plays an important part, and by separating this brake from the driving part of the instrument special modifications are possible. On the upper part of the spindle, M, a disc, O, is mounted. This

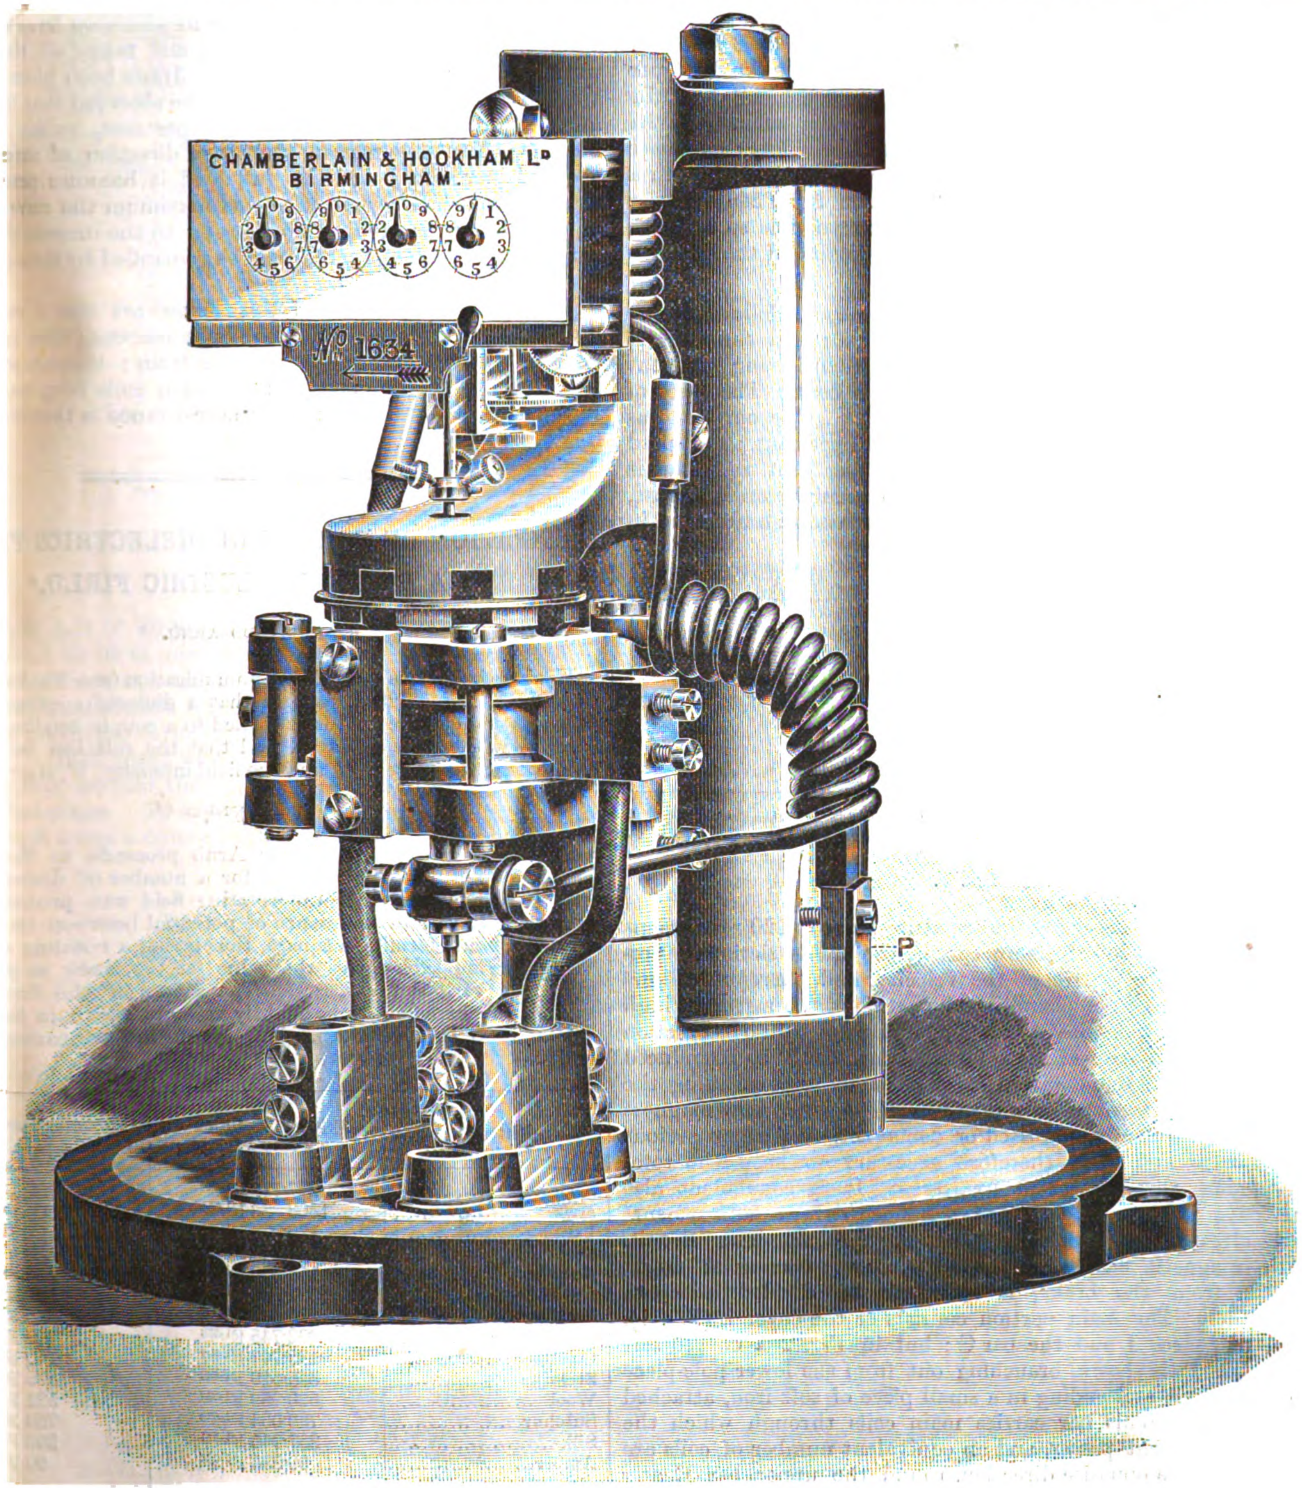

Fig. 2.

upper surface with a disc of vulcanised fibre, R. This acts as a float, and is so adjusted that with the starting current the spindle is almost in equilibrium, tending to rise, and bearing very gently against the upper jewel. The current to be measured enters the disc, N, through the mercury in which it is immersed, and passes radially to the centre, where it is carried off by an insulated conductor. It is clear that the disc will revolve in the strong magnetic field. In the earliest

is made of a special alloy of low but nearly invariable resistance. It runs between the upper part of the iron cover, L, and the pole-piece, H. Each polar surface is cut up by radial grooves as described in the early patent of 1887. The radial slots do not pass through to the centre, but leave a solid cylindrical portion which carries a considerable proportion of the magnetic flux. Radial projections on the lower pole piece (the upper part of the cover, L) embody a very interest-

Digitized by Google

ing and ingenious device. It will be seen in the engraving that these projections are notched at their bases, leaving necks or isthmuses. A considerable portion of the induction passes, as we have observed, through the centre, where there are no notches, and where therefore there are no eddy currents or brake force. The rest of the induction has a good magnetic circuit, except at the necks. The iron here becomes nearly saturated. If by any chance the permanent steel magnets become weakened, the torque between the pole-pieces of the driving armature, N, would be reduced; but the retarding force of the brake varies as the square of the induction. If no provision were made, a weakening of the torque by 2 per cent. would be accompanied by a weakening of the brake by 4 per cent. The meter would, therefore, run too fast. But as the necks to which we have referred are nearly saturated, the induction through them would vary very much less than 2 per cent. If perfectly saturated the meter would, indeed, with a 2 per cent. weakening of the magnets, run 2 per cent. slower. By careful experiment it has been found possible so to shape the notches that with any reasonable weakening of the magnets the meter will be practically unaffected.

The value of this arrangement is shown by the following test A few turns of insulated wire were wound round the magnet bars, and a current was passed through them giving sufficient ampere turns to reduce the field by 10 per cent. The speed of the meter was altered only 0·8 per cent. The current was increased until the field was reduced by 15 per cent.; the speed was altered only 1·7 per cent. The 10 per cent. reduction is probably much more than is likely to occur in ordinary use, and we are informed that no such change has been observed in any meters that have been in use.

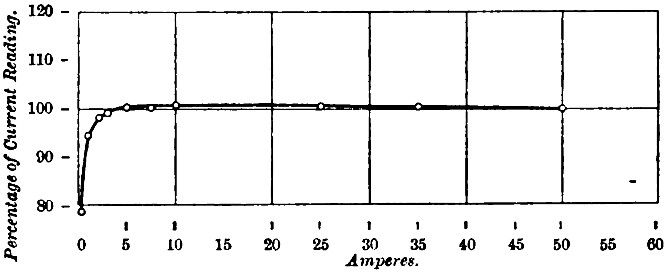

Fig. 3.

The maximum speed of the armature is about 120 revolutions per minute. While for slow speeds, the fluid friction is proportional to the square of the velocity, and therefore follows the law required for controlling the action of the meter, at high speeds this proportionality no longer holds. If no correction were made, an error of 20 to 30 per cent. would be introduced at full load. Compensation is effected by strengthening the field in which the armature revolves. The permanent magnets cannot be further magnetised or demagnetised without serious hysteresis, and it is therefore necessary to keep the total induction through them unaltered. It is convenient also to leave the brake field unaltered, since delicate adjustments are already made in this part of the magnetic circuit. The magnetic circuit of the instrument, tracing it downwards from the brake, is found to be divided into two branches. The main portion consists of the cover L (Fig. 1), the pole-piece I and the bar G; but in Fig. 2 a curved soft iron bar, P, is shown, branching out from the lower pole-piece of the brake, and ending in a small piece of soft iron, attached by a screw. This bar carries main coils through which the working current passes, and an equivalent number of coils are wound in the opposite direction, round the upper bar E at *e* (Fig. 1). This branch of the magnetic circuit is completed across the air-gap between the plate at P (Fig. 2), and the lower part of the main magnetic circuit. The curved bar and its winding is similar in all meters, and is a workshop matter; the piece of iron at the extremity forms a fine adjustment, and is carefully set in position once for all in the testing laboratory.

One more correction remains to be noticed. In all motor meters the pivot friction not only determines the starting current, but is liable to destroy the accuracy of the meter through the lower part of its range. For sensitive starting a very delicate pivot and light thrust is necessary, and it has been argued that such pivots are the weak point of motor meters, for they cannot stand the wear and tear of prolonged work. In the Hookham meter, as we have already observed, the armature spindle floats upwards at very light loads; the upper pivot is fine, and allows easy starting. But as the armature attains speed the mercury below it is flung outwards by centrifugal force, reducing the pressure and pulling the armature down against the flotation of the fibre disc to which we have already alluded. The lower pivot is strong, and takes all the hard work. The accompanying curve (Fig. 3) has been plotted from a test of a 50-ampere meter. It will be observed that it starts low, but with two amperes is only 2 per cent. wrong. At no point is there an error in the other direction of more than about 1 per cent., and at full load it becomes practically exact. If pushed beyond the rated maximum the curve would fall off, the meter running slow, owing to the increase of fluid friction at a greater rate than can be controlled by the magnetic shunt.

The main advantages of this meter are that it requires no winding up; it consumes no shunt current; there is only one moving part besides the counting train; there are no contact makers or commutators; the main coils being used only for a correction are small; and the resistance is therefore low.

DISSIPATION OF ENERGY IN DIELECTRICS PLACED IN A ROTATING ELECTRIC FIELD.*

BY RICCARDO ARNÒ.

Having shown in a preceding communication (see *The Electrician*, Vol. XXXI., June 23rd, p. 201) that a dielectric cylinder placed in a rotating electric field is subjected to a couple tending to make it rotate in the same direction, and that the relation between the energy thus dissipated, W, and the field intensity, F, is given by the empirical formula

$$W = HF^{1.6},$$

where H is a constant, Signor Arnò proceeds in the present Paper to determine this constant for a number of dielectrics. It will be remembered that the rotating field was produced by a harmonically variable difference of potential between two pairs of opposite points forming a square, thus giving a rotating resultant The following table gives the value for the work as performed upon the various dielectrics. The values in the first column assume the exponent to be slightly variable, those in the second assume it to be constant, and represent the approximate value of H:—

Material.	Exponent assumed to be slightly variable.	Exponent assumed to be constant.
Ebonite	$287·718\ F^{1.614}$	$288\ F^{1.6}$
Mica	$1308·888\ F^{1.551}$	$1309\ F^{1.6}$
Paraffin	$120·978\ F^{1.561}$	$121\ F^{1.6}$
Glass	$1388·248\ F^{1.569}$	$1388\ F^{1.6}$
Gumlac	$165·578\ F^{1.579}$	$166\ F^{1.6}$
Gutta-percha	$381·624\ F^{1.557}$	$382\ F^{1.6}$
Sealing wax	$216·383\ F^{1.557}$	$216\ F^{1.6}$
Caoutchouc	$902·745\ F^{1.573}$	$903\ F^{1.6}$
Colophony	$139·747\ F^{1.591}$	$140\ F^{1.6}$
Stearine	$325·619\ F^{1.638}$	$326\ F^{1.6}$
Wool	$520·939\ F^{1.552}$	$521\ F^{1.6}$
Sulphur	$758·064\ F^{1.628}$	$758\ F^{1.6}$
Silk	$257·946\ F^{1.551}$	$258\ F^{1.6}$
Amber	$99·284\ F^{1.633}$	$99\ F^{1.6}$

The dielectrics were moulded in the form of hollow cylinders about 3cm. long, 2·4cm. in diameter, and 1 to 5mm. thick. They were thoroughly dried and then left for some hours in the apparatus itself. The formula found is analogous to that by which Steinmetz represents the work due to magnetic hysteresis, and the results confirm the supposition that the work done in this case is due to electrostatic hysteresis.

* *Rendiconti dei Lincei*, November 12, 1893.

ELECTRIC LIGHTING AT CHATSWORTH.

A description has been sent to us by Messrs. Drake and Gorham of the generating plant which has recently been put down by them for the supply of some 850 lamps in the private rooms, corridors, and chapel at Chatsworth.

A 15in. pipe was laid, many years back, from a lake on the hills for the supply of the fountains near the house, giving an available fall of 400ft., and as this pipe, upon examination, was found to be in good preservation, it was merely necessary to insert valves at a convenient point for the supply of turbines. The turbines selected were those of the Vortex type, by Messrs. Gilkes, the larger turbines being of 50 H.P. each, and the smaller 25 H.P. The speed of the turbines was arranged to be 1,000 revolutions, so that the dynamo could be coupled direct on the same bed-plate. To avoid the complications due to the supply of current from a dynamo charging accumulators, complications which are owing to the rise of E.M.F. according to their state of charge, the switchboard has been arranged so that the small machine can be employed for charging the accumulators, while the house circuit is run direct from the larger machines, which are connected either singly or in parallel as required. The arrangement also provides for the small machine and the accumulators being worked together in case of emergency for the supply of the house. Precautions are taken in the switchboard to prevent any accident due to the switches being moved in the wrong order. The dynamos were made by Messrs. Siemens Bros. and Co.

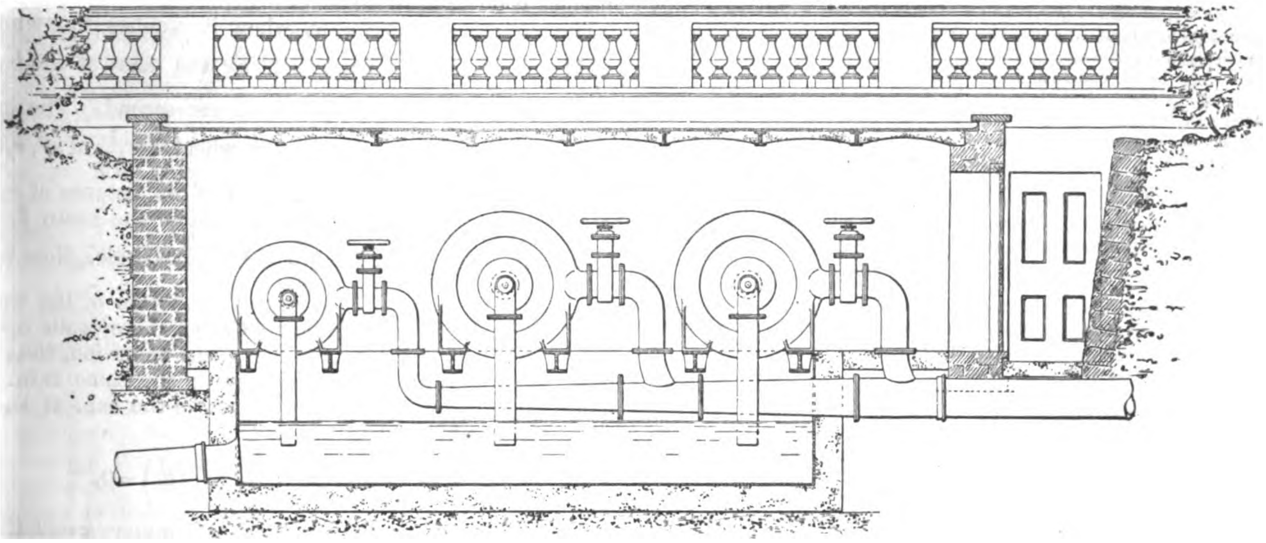

Fig. 1.—Side Elevation of Turbines.

Owing to the high fall available, special precautions had to be taken to prevent any sudden stoppage of the water, which would produce a jar on the pipes. A previous attempt to provide a valve at the lower end of the pipe so as to avoid having to climb the hill whenever the fountains were required, had entirely failed from this cause. To meet this a 3in. by-pass is provided for every valve, so that after the main valve has been closed, the by-pass can be manipulated. This expedient has been found to be thoroughly successful.

The current is conveyed to the house by means of armoured cables more than half an inch in sectional area. This cable leads to the main distributing switchboard in the centre of the building, from which point all the distribution is effected by means of a number of small circuits; a pilot wire being brought back from this point to the dynamo room to enable the engineer to keep the voltage constant at the point of distribution. The voltage at the house is maintained at 105, and the whole of the wiring is on the parallel system. The accumulators are of the "D.P." type, capable of discharging at 120 amperes for four hours. Endeavours have been made to simplify the arrangements and to avoid all complicated apparatus. The work was carried out by the contractors with the assistance of the Estate staff, working under the direction of Mr. Martin, the agent, and Mr. Woodhead, the Clerk of Works.

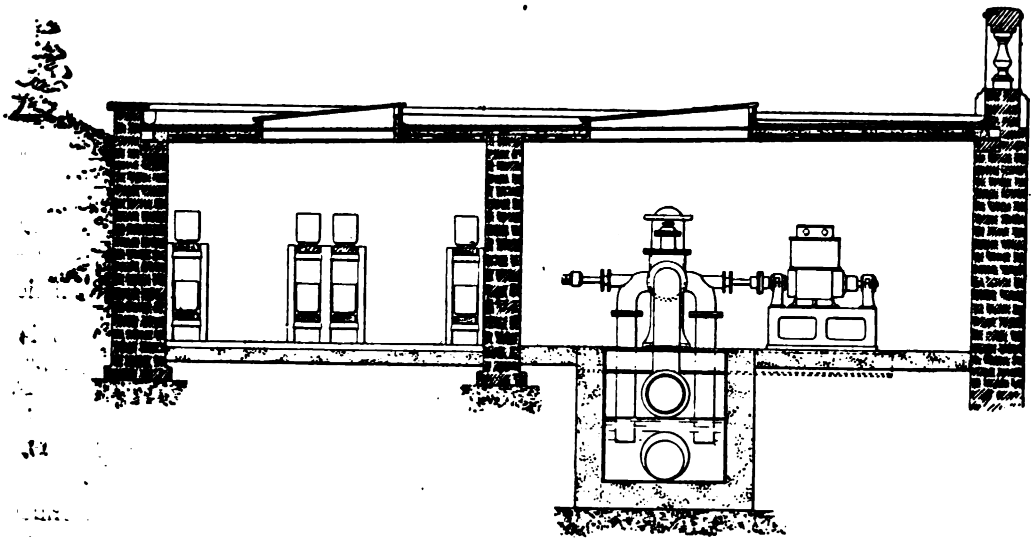

Fig. 2.—Section, showing Accumulators, Turbine, and Dynamo.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

C. B. Harness, Managing Director of the Medical Battery Company, J. M. M'Cully, and C. B. Hollier, surrendered on Wednesday to their bail before Mr. Hannay, at Marlborough-street, to answer the charges of having conspired together to obtain money by false pretences from various persons.

Mr. T. E. GATEHOUSE was recalled and further cross-examined by Mr. Avory. He said he would recommend the use of electricity for neuralgia and paralysis of the arm or any limb of the body. He did not know that he would recommend electricity for any other diseases. From experiments he had made during the last five weeks, he found that a Harness belt would not contract the muscles or nerves of recently-killed frogs. He came to the conclusion that one milliampere was the minimum dose of electricity to be given, because the nerves of the human body were less sensitive than those of frogs. He was of opinion that a current of one milliampere would produce no effect upon the body unless repeatedly made and broken. The current to be obtained from a Harness belt applied to the average human body (when properly connected) would be from one-hundredth to four-hundredths of a milliampere. Even if the body were very moist, in his opinion the current would not amount to two-tenths of a milliampere. It would not amount to one-tenth unless artificial moisture was applied. He thought Mr. Joel said in his evidence that from a belt worn on his own body he had obtained a current of two-tenths of a milliampere, and he also stated that he measured the resistance of the human body with a Wheatstone bridge and a battery, which was an entirely fallacious method. He did not dispute that the belt might ring a bell without the use of a concealed battery by the aid of an electrolyte. The sores were produced by the chemical action of the perspiration on the zinc, which produced oxychloride. He agreed with Dr. Lewis Jones that impurities in the zinc in the presence of moisture would produce electricity, and ordinary commercial zinc did contain impurities. As soon as the webbing of the belt got saturated with the moisture of the body the electricity passed through the webbing and not through the body. He had proved that by experiment. He looked upon Dr. Harries as an authority upon electro-therapeutics, and he coupled him with Dr. Lewis Jones in his Paper. He had no knowledge of what Mr. Lynd knew about electro-therapeutics. He could not say whether he described Mr. Lynd in 1887 or 1888 in the *Electrical Review* as a gentleman who had made electro-therapeutics a special study. Until Mr. Lynd was in the witness-box in the present case he did not know that he had set up an establishment similar to that of Harness. He believed he heard Mr. Lynd admit having written the letter of December 8, 1886, produced. The witness, after reading it, confessed that he did not understand its contents. He understood that Mr. Lynd in that letter recommended that belts should be made without any metal connection between the zinc and the copper.

Mr. R. W. SELLMAN was recalled, and his examination-in-chief continued: He said he knew Sharman, who had been the advertising manager at Oxford-street, for the last three or four years. He knew there was an association connected with the premises called the British Association of Medical Electricians, and he believed Mr. Harness, Dr. Carter Moffatt, and Mr. Sharman were members of it. Six years ago the witness was present as a vocalist at the *matinées* given at 52, Oxford-street. He used to sing there daily. He saw, to the best of his knowledge, bells rung by belts. He did not see how it was done, because he was in a back part of the room. He saw incandescent lamps lighted.

At this point Mr. HANNAY again adjourned the case for a week, allowing the defendants the same bail as before.

Edison-Bell Phonograph Corporation v. Edison Phonograph Company.

Mr. Justice Day, in the Queen's Bench Division last week, heard an application made by the representatives in this country of Mr. Edison, seeking an injunction restraining the "Edison Phonograph Company" from infringing two patents, the property of the Edison-Bell Phonograph Corporation.

The defendants did not appear, and the plaintiffs obtained judgment with costs, the damage sustained by the plaintiffs to be ascertained.

CORRESPONDENCE.

MOTIVE POWER AND GEARING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like to suggest that, in the interesting discussion between Mr. H. T. Brydon and Mr. E. Tremlett Carter, found in your last week's Correspondence column, a definition of the point at issue is missing, viz., the definition of Force. Mr. Brydon argues that, if force and resistance are equal, no work can be done; and Mr. Tremlett Carter says: "His statement is simply untrue and opposed to the facts of dynamics," and also, "To every action there must be an equal and opposite re-action. This is universally true, whether of bodies at rest, in uniform motion," . . . &c.

It occurs to me to ask: Does the latter statement represent "facts of dynamics," or does it represent fiction of dynamics?

In dynamics Force is by definition $M\frac{L}{T^2}$. Since time enters into the force of dynamics, this force can not exist apart from motion. In words: Force is the length-rate of change of energy.

A body of falling water transmits energy on to the water-wheel; that changes it on to the flour disintegrator; that changes it on to other matter.

The energy in the water, when it reaches the wheel, is $\frac{1}{2g}Mv^2$ foot-pounds, M representing the mass of the body of water in lbs., v its velocity in feet per second. The energy in the water, when it leaves the wheel, is $\frac{1}{2g}Mv_f^2$, v_f being then the velocity of the water. If L be the distance of contact between water and wheel, in feet, and F the mean force of the transmission, then $F=\frac{1}{2g}M\frac{v^2-v_f^2}{L}$ pounds. Now for the equal opposite force: The direction of motion of the water is the direction of F. By Tremlett Carter there is an opposite equal force. This means, by the given definition, that there is an opposite exchange of energy at the same rate. The resulting change rate of energy must be the sum of the two, hence the resulting force,

$$F_s=\frac{1}{2g}M\left(\frac{v^2-v_f^2}{L}-\frac{v^2-v_f^2}{L}\right)=0.$$

It is safe to predict that under these circumstances, the rate of change of energy being zero, the rate of the flour-production will also be zero, which is in accordance with Mr. Brydon's suggestion.

There is yet a simpler way of wording the meaning of the equation—

$$F=\frac{1}{2g}M\frac{v^2-v_f^2}{L}$$

The force is the diminution of the v^2 of the water per foot of its journey in contact with the wheel. *Ergo*, the equal opposite force must be an equal increase in the v^2 of the water during the same journey. Result: the water must leave the wheel with the velocity with which it reached it, and no work can be done in the mill unless the mill be a *perpetuum mobile*.

Experience shows, however, that the water loses velocity, and the temperature rises in the things inside the mill. If we read Clausius, we find that the temperature rise means an increment in the v^2 of the molecules of the things, which, when multiplied by their mass, brings out the same quantity of energy which the water lost through the length L.

But to say that, at the action of the water on the wheel, there is an equal reaction, and then to let action and reaction stand as the equivalents of a force and an opposite force of dynamics, where force is $M\frac{L}{T^2}$, is pure fiction.

Perhaps Mr. Tremlett Carter's force is not at all the equivalent of the length-rate of a change of energy.—Yours, &c., F. V. ANDERSEN.

14, Westdown-road, Catford Bridge,
London, S.E., December 26, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I may satisfy Mr. Andersen that "Mr. Tremlett Carter's force" has the dimensions MLT^{-2}, as required by him. There is no specific difference between "the force of dynamics" (as Mr. Andersen calls it) and any other force; the dimensions of all forces are the same, and their relation to energy and motion identical. I would submit that if the total effort in any case is greater than the total resistance, then the energy expended by the effort is greater than that absorbed by the resistance; and, as a consequence, the energy lost by the acting body is greater than that acquired by the resisting body, so that energy is annihilated, and the doctrine of conservation cannot be applied to energy.

Digitized by Google

When Mr. Andersen carefully adds the energy expended by the water to the energy absorbed by the flour mill, giving the one a positive and the other a negative sign, he discovers what is perfectly true, namely, that that sum is equal to zero. But when he assumes that because the sum is zero therefore no flour will be ground, he is unscientific. He might as well say that if I spend £10 and a shopkeeper receives the £10, then, giving the one £10 a positive and the other a negative sign, since the two added together are equal to zero, it is impossible I can have bought anything.

Once again let me appeal to Newton's laws of motion, which, despite the bad logic of paradoxists, have not yet been shaken. It can be shown experimentally that if we take a mass, M, and act on it with a constant force, f_1, at the same time opposing its motion by a lesser force, f_2, both forces acting in the line of motion; then the acceleration of the mass will be

$$a=\frac{f_1-f_2}{M},$$

whence $$f_1=f_2+M\,a.$$

Now, the dimensions of a are $L\,T^{-2}$, so we may express this as $$f_1=f_2+M\,L\,T^{-2}.$$

By Mr. Andersen's own showing $M\,L\,T^{-2}$ is the expression for force. Call this force f_3; then

$$f_1=f_2+f_3.$$

Now I, in common with most if not all writers on the subject, call the force f_1 the *total effort*; I call the force f_3 the *inertia resistance* of the mass; and I call the sum of f_2 and f_3 the *total resistance*. Whether it is "pure fiction" to say now, on the basis of these definitions, that the total effort is always equal to the total resistance, I leave it to Mr. Andersen to judge.—I am, &c., E. Tremlett Carter.

December 28, 1893.

COLOGNE CENTRAL STATION STATISTICS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Herr Feldmann's figures are interesting as showing the best figures that have as yet been obtained in Germany—still, in spite of your remarks, I do not think we English engineers have much to fear from comparison. Cologne has a good load factor, fuel is cheap, and as management charges are shared with the gas and other departments, they can be kept low as at Bradford. Still, taking the figures as they are, Herr Feldmann's figures for the year ending March 31, 1893, do not compare well with the Bradford half-year ending June, 1893, or the Liverpool figures ending December 31, 1892, as the attached small table shows very clearly.

—	Cologne. 310,000 units.		Bradford. 410,540.		Liverpool. 796,281.	
	Sum spent.	Per unit.	Sum spent.	Per unit.	Sum spent.	Per unit.
	£ s. d.	d.	£ s. d.	d.	£	d.
Coal	990 16 0	0·766	486 0 1	0·282	2,430	0·73
Water and petty stores	133 16 0	0·106	62 4 8	0·036	500	0·153
Wages	963 17 0	0·746	580 0 0	0·34	1,260	0·382
Repairs & maintenance	1,067 3 0	0·91	406 10 7	0·237	1,891	0·599
Management and other expenses	1,374 16 0	1·06	474 0 0	0·277	1,891	0·599
Total	4,518 8 0	3·5	2,008 16 3	1·17	8,052	2·42

Even when we compare several items with corresponding items of our London stations of equal output for half-year ending June, 1893, Herr Feldmann's figures are nowhere.

—	Cologne: 154,900 units.	Knightsbridge: 152,176 units.
	d.	d.
Coal	0·76	0·64
Water, &c......................	0·106	0·08
Wages	0·746	0·21
Repairs and maintenance	0·91	0·66
Total works cost	2·52	1·59

The price of fuel at Cologne is about 14s. 6d. a ton, and at Knightsbridge £1. 0s. 6d. The load factor at Cologne is 16 and at Knightsbridge 12. The actual weight of fuel used is 11·8lb. per unit at Cologne and 5·8lb. per unit at Knightsbridge.—Yours, &c., R. E. Crompton.

AIR CORE TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I observe in your issue of November 3rd a brief abstract of Mr. E. C. Rimington's Paper on "The Behaviour of an Air Core Transformer when the Frequency is below a Certain Critical Value," in which is brought forward the phenomenon of increased impedance and consequent decrease of current in the primary circuit, observed on closing the secondary circuit under certain conditions, which, for a particular case, are given in the Paper.

Although obvious to many, it may be of some general interest to state that the effect may generally be observed by anyone possessed of patience and a small induction coil of the usual pattern. The break, of course, must be disconnected and the primary excited by alternating currents.

About four years ago the phenomenon was observed at the laboratory of Prof. Elihu Thomson, and a note-book has a note, under date of December 31, 1889, a transcript of which is as follows:—

"December 31, 1889.

"Put primary of small Rhumkorff coils in series with nine lamps arranged in multiple arc, thus exciting it with an alternating current of about 10 amperes. When secondary circuit of coil was closed through Geissler tube, or conductor having high resistance, marked fall occurred in candle-power of the lamps used as resistance in the primary circuit. The impedance of primary was thus apparently increased; when secondary was closed through very low resistance, lamps brightened as usual."

The coil referred to, when used with break, gave about $1\frac{1}{4}$in. sparks; it was about 7in. long, secondary wound with No. 32 wire. The primary winding consisted of two layers No. 11 (0·09in. diameter) wire. Core was made up of exceedingly fine iron wires, and was one inch in diameter. The frequency was that at which the alternators of the Thomson-Houston Electric Company were run, *i.e.*, 125 periods per second.

The Geissler tube referred to was intended for use as a short-circuiting device; it was fitted with electrodes that came quite near together midway of the length inside the tube. A water rheostat was used for resistance.—Yours, &c., R. Shand.

Lynn, Mass., December 5, 1893.

THE PAST YEAR'S WORK.

Messrs. Anderson and Munro.—Like the majority of Glasgow firms, business has been brisk during the past year with Messrs. Anderson and Munro. The installation at the Clydesdale Bank consists of nearly 400 16-c.p. incandescents, and is noticeable for some excellent electrolier work executed by Munro's Electrical Manufacturing Company. One pendant electrolier of polished brass work is fitted for 40 lamps. The installation is nearly completed, to the plans of Dr. J. T. Bottomley, F.R.S.

Messrs. Clarke, Chapman and Co.—An extensive list of electric lighting installation contracts carried out by this Company during the past year includes no less than 25 large vessels, amongst them the cable steamer "Mackay-Bennett," for the Commercial Cable Company. Messrs. Armstrong, Mitchell and Co. have entrusted the lighting of seven of their new vessels to the Company. In addition to ship-lighting, for which the firm have special facilities, the list includes the lighting of the large dye works at Holmhead; the supply of two complete Suez Canal plants for Messrs. W. C. Martin and Co.; the lighting of Eldon Colliery, Bishop Auckland, including a pumping plant; and the docks, shops, and offices for both the Wallsend Slipway and Engineering Company and the Mercantile Dry Dock Company at Jarrow.

Messrs. Drake and Gorham.—In a review of the work of the past year this firm have to record very satisfactory progress, the amount of business representing nearly 150 installations, representing about 13,000 16-c.p. lamps. This list includes an extensive installation at Chatsworth for the Duke of Devonshire, 850 lights; Callaly Castle, 600 lights; Rhinefield, 550 lights; Great Northern Railway Company's new offices, 650 lights; the head offices of the Bank of England, 550 lights; the remainder averaging from 80 to

Digitized by Google

400 lights. The Chatsworth installation includes a Turbine Plant, and the motive power in many of the installations is a Petroleum, Gas, Steam, or Turbine Plant.

MANCHESTER EDISON-SWAN COMPANY (LIMITED).—We have received from this Company a formidable list of installations carried out during 1893, consisting in all of 60 installations, not reckoning those nearly completed or just commenced. The list includes many of the principal business premises in Manchester, Blackpool, Preston, Liverpool, Rochdale, &c., in addition to the Blackpool Winter Gardens, the Literary and Philosophical Society, Manchester, the Royal Infirmary, Manchester, the Great and Little Co-operative Societies at Bolton, Prince's Theatre of Varieties at Reading, from which it will be seen that the Company, notwithstanding the general depression, have been fairly well occupied during the past year.

MESSRS. J. H. HOLMES AND CO.—During the past year this firm have built more than 170 dynamos of the "Castle" type for use in lighting, power transmission, and electro-deposition, varying in size from one-half to 200 E.H.P., the total combined output being 2,343,335 watts, equal to 3,141 E.H.P. The firm have been especially busy in ship lighting, and several of the largest vessels built during the past year have been fitted complete. Mill lighting contracts have included cotton spinning mills at Ashton-under-Lyne, Heywood, near Manchester (2), and Stockport. A 1,500-light contract has been carried out for Messrs. Walker, Reid and Co., at Dunfermline. Considerable attention has been paid to the production of the firm's latest type of drum-bar dynamo, in which machine the armature conductors, having to take heavy currents, are made in the form of laminated copper bars, connected across by means of spiral end connections. These armature cores are built up of thin discs of the best Swedish charcoal iron, and are insulated from each other with paper to prevent undue heating. A fan is mounted on the shaft, causing a current of air to pass through the core. A machine of this type of 120-unit capacity has been built for the Aluminium Company at Oldbury, and, when tested by Prof. A. B. W. Kennedy, gave an efficiency of 98 per cent. Amongst the contracts in hand is one for Messrs. Joshua Smith (Limited), of Manchester, for 1,100 lights; the Vulcan Spinning Mill, at Bury, 1,060 lights; and four large sugar mill installations in the West Indies. It will be seen that Messrs. Holmes and Co. have obtained their fair share of the work of the year in all parts of the world, as, of three large mill installations in the list one is at Nicaragua, another in Java, and another in South America.

MESSRS. MAVOR AND COULSON.—This Glasgow firm have been very busy during 1893, and included in the heavy contracts obtained is one for an installation of 3,000 16-c.p. incandescents for a woollen factory at St. Petersburg, about half of which has been completed, including the supply of the necessary plant, apparatus, &c.

MESSRS. RUSSELL AND CO.—This firm notify us that during 1893 a fairly brisk business in installation work has been done, including country and town houses, shops and factories, &c. The contracting business of Mr. Medhurst, at Cambridge, which was taken over in August last, has brought in a number of orders for Cambridge and district, including some from the Clare College authorities and the Corporation. In anticipation of the skating season a large field in the neighbourhood is being temporarily installed with the electric light.

WOODHOUSE AND RAWSON UNITED (LIMITED).

The following is a list of the principal creditors in this failure. The actual number of creditors over £10 reaches the formidable total of between 270 and 280. It will be seen that, owing to the very large number of firms to whom Messrs. Woodhouse and Rawson extended their favours, only in a few cases does the amount of indebtedness reach a considerable sum. The bankers' claim is unusually small :—

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES DIRECTORY AND HANDBOOK" contains over 1,000 pages, several new and handy features having been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

The 1894 Edition is in preparation, and will be published in January. *New names, alterations of addresses, &c., should be sent in at once.* Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, which has a special interest at the present time, is now ready, and will be forwarded on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus can be obtained on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready, and will be sent direct on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus will be forwarded free on application.

TENDERS INVITED.—The Swansea Harbour Trustees invite tenders for the working, maintenance, and renewal of their electric light machinery and plant for five years (subject to earlier determination by the trustees). Particulars of Mr. Strick, Harbour Offices, Swansea.

TENDERS ACCEPTED.—The following tenders have been proposed for acceptance by the Highways Committee of the Sunderland Corporation for the supply of plant and apparatus for the introduction of the electric light into the borough. At the next meeting the Town Council will be asked to confirm the acceptance of these tenders, and to grant the committee permission to raise a loan not exceeding £25,000 for the carrying out of the whole scheme. The total amount of the tenders is £15,074, against an estimated sum of £21,000. Boilers and mountings, Hawkesley Wyld and Co., Sheffield, £1,380; engine and dynamos, Messrs. J. H. Holmes and Co., Newcastle, £4,340; motor alternators, Carlton Company, Chelmsford, £1,352; batteries, Electrical Power Storage Company, £763; insulated cables, India Rubber Works, Silvertown, £2,592; road work, Messrs. Simpson, Newcastle, £2,590; ironwork, Messrs. McLaren, Glasgow, £296; stonework, Messrs. Wilks and Maplebeck, Birmingham, £236.

CHANGE OF ADDRESS.—Major-General Webber, C.B., consulting electrical engineer, has removed his office from Portland House, Basinghall-street, E.C., to No. 27, Chancery-lane, London, W.C.

EXTENSION OF BUSINESS.—Messrs. Smiths and Co. (Limited), of George-street, Edinburgh, have added an electric lighting branch to their old-established business of lamp and oil dealers, under the management of Mr. W. Finlay.

DISSOLUTION OF PARTNERSHIP.—Messrs. H. C. H. Smyth and R. E. Holdom, carrying on business as electrical engineers, at 2, Great Russell-street, London, W.C., under the style of Smyth, Holdom and Co., have dissolved partnership. The business will be carried on by Mr. Smyth.

BANKRUPTCY.—A receiving order has been made in the estate of Free Chilton, carrying on business as an electric, cycle and general engineer, at 19, Adelaide-street, and Wellington-street, Luton.

ELECTRIC LIGHT CARBONS.—It has long been a reproach that the carbons used in this country for electric lighting are all supplied either from the Continent or from America. It has been for some time past in contemplation to erect a carbon factory in England, and the English Electric Carbon Company (Limited), of Brymbo, near Wrexham, has been formed with this object. The Company have decided that, for the present, only carbons of the highest quality, equal to the best Continental brands, are to be manufactured. The chairman of the new Company is Mr. J. H. Darby, the remaining Directors being Sir H. B. Robertson, and Messrs. J. C. Edwards, W. Darby, and Emil Mahla. The secretary and manager is Mr. T. G. Littleboy.

ELECTRIC POWER IN WELSH MINES.—Amongst other recent improvements at the pits belonging to the Aberdare Merthyr Collieries Company, electricity has taken the place of steam-power for working the pumping arrangements below ground.

"CONSTANTINOPLE IN LONDON."—We illustrate below some special designs of lamps and lamp fittings, used in the lighting of the extensive show now being held at Olympia, London. These lamps and fittings have been manufactured by Messrs. Benham and Froud (Limited) from the designs and under the supervision of Mr. R. M. Laws, the Company's manager. There can be no doubt that these elaborate displays, if not almost impossible without the aid of the electric light, are at least rendered doubly effective by its use. It is to meet an actual demand that Messrs. Benham and Froud have incurred heavy expense in manufacturing this special type of fittings for "Constantinople in London," and

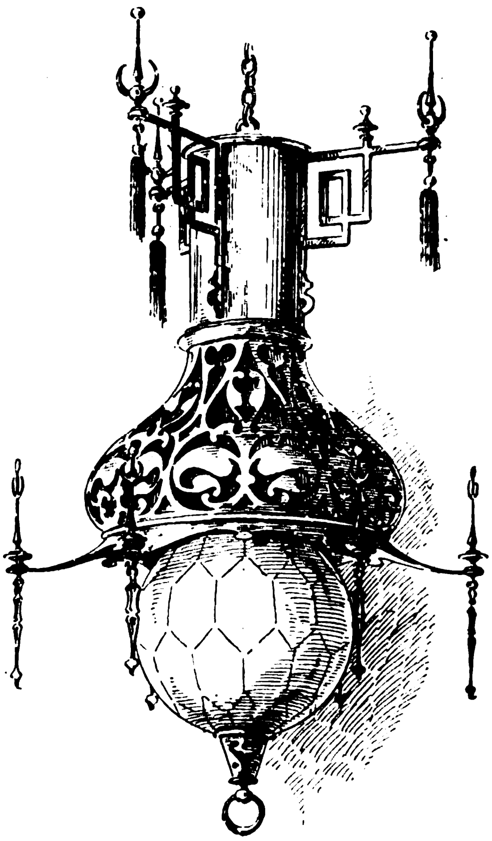

FIG. 1.

doubtless this enterprise will find ample recognition in the future in the adoption of similar artistic fittings for other national displays, which will doubtless follow "Venice" and "Constantinople." The firm have had great experience in this class of work, and in no case have they been more successful than at Olympia. The effect of the magnificent show is considerably enhanced by the remarkable fidelity to the general surroundings shown in the special designs under

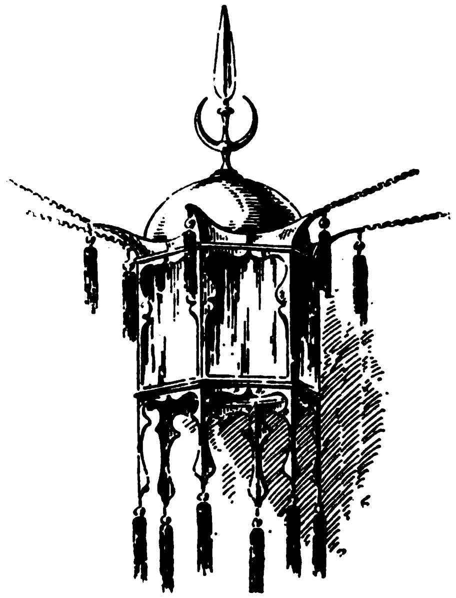

FIG. 2.

notice. Fig. 1 shows a large polished brass cover for arc lamps, perforated, and lined with transparent ruby drop rings, drops, and outer brass brackets, with crimson tassels. Fig. 2 is a brass lamp suspended across the streets by copper-coloured chains. These lamps have dark ruby domes, polished spears, crescents, and crimson tassels. In addition to the above, brackets are

Digitized by Google

used for the streets and corridors, of hammered iron with brass and copper lanterns, and brass lamp-posts for the streets, bridges, &c. Quite an extensive variety of these special fittings are used at the exhibition.

Duplex Nozzles v. Solid Jets.—Messrs. Meldrum Bros., of Manchester, send us the results of some comparative tests of duplex or ring jets, and of plain solid jets of steam for forced draught for steam boilers. They claim that the solid jet is greatly superior.

Omnibus Lighting.—With regard to the paragraph on omnibus lighting in our "Trade Notes" last week, we are asked by the Bristol Electric Safety Lamp Works to state that the summonses at Bow-street were not due to any fault or weakness whatever of their battery, but solely to the insufficient time allowed for charging. The London General Omnibus Company's solicitor substantiated this when the first summons was heard, by stating that "the system acted admirably during the summer months," where there is apparently the same amount of vibration present as during the winter. As the Bristol Works are not light contractors to the London General Omnibus Company, but have only to keep 140 accumulators up to a specified efficiency, there can be no doubt that they are not responsible for the absence of a complete set of spare batteries which would give ample time for inspecting and charging. With regard to Mr. Elliott's letter the Bristol Company say that "any maker can, of course, construct a 40 hours' (what voltage ?) battery, but the question is of what weight, of what dimensions, and with what durability. Mr. Elliott does not supply these data, but should he or anybody else think that he can beat us we should only be too glad to submit a battery for competition on fair ground."

The General Electric Company's Catalogue.—We have received a new edition of this very complete catalogue. Several additions have been made, including a section on heating and cooking apparatus, and particulars of the various kinds of "Robertson" lamps. The section on telephones, which contains many useful diagrams of connections for various inter-communication systems has been revised. The catalogue consists of seven sections, viz., electrical supplies, plant, fixtures, cooking, bells, telephones, and medical apparatus. Tags are fastened to the margins at the beginning of each section, greatly facilitating reference to any particular part.

Diaries, &c.—We have received from the Brush Electrical Engineering Company a very convenient and excellently bound pocket diary, with pencil.

——— The Electrical Power Storage Company (Limited) have again adopted the useful large-size blotting pad and index diary for 1894, in addition to the useful postal information and calendar. Some tabulated particulars are given of the E.P.S. accumulators and apparatus.

——— The "Indian Engineers' Diary and Reference Book," issued from the English office of our contemporary, the *Indian Engineer*, is a demy 4to diary, interleaved with blotting paper, and containing many useful memoranda and engineering tables, including several conversion tables for Indian weights and measures.

——— We have also received a copy of the 1894 edition of "The Mechanical World Pocket Diary and Year Book," which contains forty per cent. of entirely new matter of a practical character. The sections of information deal with steam-engine practice, gearing, structures, pumps, hydraulic machinery, &c. The diary has 50 illustrations, and is issued in a handy form.

——— Mr. J. W. Vickers, of Nicholas-lane, Lombard-street, E.C., sends us a useful hanging sheet month-at-a-glance calendar, neatly printed, and containing face calendars for 1893, 1894, and 1895.

Brighton.—A discussion took place at the last meeting of the Town Council as to the rental to be derived by the Corporation from the Sea Shore Railway. The question of a poll tax, rental, or royalty having each in its turn received approval and condemnation, after Mr. Volk had explained that the Directors of the Sea Shore Railway Company could not entertain any idea of a royalty, and having expressed his surprise at the obstruction thrown in the way of the undertaking, the recommendation of the committee that a rental of £25 per annum be agreed to was accepted.

——— The demand for electric current from the Corporation's mains continues to increase so satisfactorily that, although very considerable additions have been made to the electric-lighting plant during the present year, still further extensions will, it is anticipated, be shortly necessary. The recent additions to the plant include three large boilers, capable of doubling the boiler capacity at the works, one new engine, and one dynamo ; and another engine and dynamo are on order.

Bristol.—The electrical committee of the Town Council at their meeting last week discussed the quesion whether Mr. Proctor, the resident engineer, should be allowed to employ improvers and to receive premiums. The matter was discussed on a previous occasion, when, by a small majority, it was decided against Mr. Proctor, but notice was given to rescind this resolution, and this motion was discussed at the present meeting. The committee decided to so rescind the previous resolution, and discussed a variety of proposals, one of which was that the premium should be fixed at £100, one half of which should go to the city authorities, and the other half to the engineer. Apparently, no definite decision was arrived at.

——— The *Western Press* understands that with regard to the extension of the lighting of Bristol, while the public lighting cannot be enlarged, Mr. W. H. Preece is of opinion that the incandescent lighting cables are capable of supplying three times the present load. The amount expended on the electric lighting scheme up to the middle of December was about £80,000, which is £3,000 in excess of the original estimate. The demand for the light is growing, and has much exceeded Mr. Preece's early anticipations. Mr. Preece is of opinion that, at the present rate of growth, the Corporation will be realising a profit 12 months from the commencement of the lighting. It is pointed out to the Council that they will undoubtedly have to contemplate extensions in the near future, and that, sooner or later, the capital for the scheme must be raised to £100,000, and that by this additional expenditure, considerably increased profits will result.

Chelmsford.—The adjourned special meeting of the Town Council, held last week, finally approved of the application by Messrs. Crompton and Co. for a Provisional Order for a period of 42 years for the public and private lighting of Chelmsford, the only modification being an amendment to Clause 80, dealing with the question of purchase. In the event of a sale, the Chelmsford Electric Lighting Company is to sell to the local authorities all buildings, lands, and plant as may be necessary for the public and private lighting of the town. A clause is inserted giving the Council power to purchase at the expiration of 21 or 31 years.

Chiswick.—The Local Board have received from the Board of Trade a copy of proposed regulations for the electric lighting of Chiswick. The Works Committee have the matter in hand.

Church Lighting.—It seems likely that the introduction of the electric light into the Bristol churches will become general. We recently announced that the light had been installed in Broadmead Chapel (Bristol); and now the churchwardens of St. Nicholas have instructed Messrs. King, Mendham and Co. to instal the light throughout the church. The present gas fittings are to be to some extent utilised, and consist of three massive chandeliers. The screens are also to be fitted with small lamps for the lighting of the choir, and the belfry and clock are also to be illuminated. To the latter the current will be automatically switched on and off by a movement in the clock.——St. Paul's Church, Bray (Ireland), has been lighted electrically, the current being obtained from the local electric light and power station.——Elgin-place Congregational Church, Clydeside, is to be lighted by electricity.

Coventry.—The Electric Light Committee's report to the City Council was discussed at the last meeting. The Committee have considered Mr. R. Hammond's specification and general conditions of the installation of the generating and distributing plant, the amount of the contract being £9,485, exclusive of the trenching of streets, the work for which the Corporation will themselves provide. The Committee's report was adopted, and a letter was read from Messrs. Fowler and Co. (Limited), of Leeds, explaining the connection of Mr. Hammond with that Company.

Dewsbury.—At the meeting of the Co-operative Society of Ravensthorpe, near Dewsbury, the President said that the question of introducing the electric light into the stores had been under the consideration of the Directorate for some time. The Halifax Flour Society had saved 50 per cent. on their gas bill by the introduction of the electric light. He estimated the cost of introducing the light at about £350, as it will be necessary to put down additional motive power. A resolution to the effect that the electric light be adopted was carried.

Douglas and Laxey Coast Electric Tramway.—Although the Company for working this tramway is not yet floated, sufficient progress has been made to warrant the promoters in anticipating that the tramways will be completed by June next. The works are being carried out by Mr. F. Saunderson, C.E., of Douglas. Messrs. Mather and Platt are supplying the plant. Mr. J. Aldworth is the Manager.

Dundee.—Messrs. Burt and Co. have secured the contract for lighting the Dundee Exhibition by electricity. The motive power will be supplied by a powerful "Acme" gas engine, similar to that used at the Celtic Park installation, Bristol.

Ealing.—The Local Government Board, having sanctioned the borrowing of a sum of £25,000 for electric lighting purposes, the Finance Committee of the Local Board recommend that application be made to the Local Government Board authorising them (the Ealing Board) to raise the sum of £50,000 by the creation and issue of Local Board Stock. This recommendation was not adopted at the last meeting, but was deferred for consideration at the next meeting.

Digitized by Google

Electrical Engineers as Mining Agents.—It is something of a novelty, says *Industries and Iron*, to find an electric lighting company promoting what is practically a gold mine. The Redding Electric Lighting Company of Shasta Co., Sacramento, U.S.A., intend to complete the dam which it has put in for power purposes, and to use the races which run parallel to the Sacramento river as the river bed for a time, so that the rich gravel below the dam may be worked for gold. In addition to this the company contemplates continuing the races by ditches to a neighbouring agricultural district, Cotton Wood, for irrigation purposes, and to interest outside capital in this irrigation scheme. Wires will be run from the Electric Light Company's power-house, and the work by night will be accomplished with the aid of arc lamps strung along the river.

Electric Light in a Prison.—The electric light has been introduced into the prison of the little town of Vaetz, a few miles from Buda Pesth. Every cell is illuminated.

Night Work.—The St. James's Vestry (Westminster) are to discuss at their next meeting a motion that a condition prohibiting the carrying on of operations during the night and early hours of the morning be attached to consents given by the Vestry to electric lighting companies for the carrying out of works involving the disturbance of the public streets.

Electricity in the Theatre.—The *Era* contains a description of a new device used at Abbey's Theatre, New York, on the occasion of Mr. Henry Irving's production of "Becket":—

The "table" was installed by the Cushing Electric Company of Boston. The principal device is one whereby any combination of effects can be obtained before the change takes place, and then the whole change made instantaneously by one sweep of a main lever. The effect is obtained by throwing the different circuits in operation through the switcher, having first sent all the current through the rheostat. Every rheostat can be controlled by the main lever, and when the proper moment arrives, it is only necessary to operate the lever to produce the desired effect. The Abbey switchboard is elevated to perhaps a dozen feet above the stage floor. This is a desirable feature, as there is no danger of the handles of the switches or other paraphernalia on the board being broken during the shifting of scenery in a dark change. The stage manager stands below on the stage, and signals the electrician above just what to do by means of push buttons, which throw into operation pilot lamps, whose colours and positions are equivalent to the lamps in the borders, bunches, or foots. The board also possesses a larger number of "points" on its rheostats than any other board in any other theatre, except, perhaps, the New Metropolitan Opera House, where there is a larger board of the same design. This enables a much more gradual reduction of light to be made, the desirability of which can be readily understood. A feature of the pilot lamps is that they do not burn in connection with the main circuit which they represent, except when especially turned on with a switch of their own. The reason for this is that the number of pilot lamps is very large, and during a dark change the amount of light they would diffuse would be so great as to mar the effect of the scene; hence, although the circuit in the front corridors might be in operation, yet the pilot lamp would not show it unless the workman desired it to do so. In addition to the electrical features of the board, there is a perfect tube system whereby any part of the house may be reached by the stage manager, or *vice versâ*. Another ingenious device is the new orchestra lamp for use during a dark change. At the top of each music desk is a cylinder in which is contained two 16 candle-power incandescent lamps. The cylinder has a quarter-inch slit along its entire length, and when placed at a certain angle sheds light all over the page of music, while all around it is dark. The effect is very good, and far better than could be obtained from the ordinary shade. The device is patented.

Fleetwood.—As indicated in our last issue, the tender of the Brush Electrical Engineering Company has been accepted for the lighting of Fleetwood. At the meeting of the Improvement Commissioners, at which the tender was accepted, it was pointed out that only £70 had been spent in preliminary expenses. A resident electrical engineer is to be appointed.

Football by the Electric Light.—Notwithstanding the fog, a very successful football competition was held at the Celtic Park, Glasgow, on Christmas evening, at which about 5,000 spectators were present. The electric light was installed in the large private field in which the match took place, and sufficient light was provided by sixteen arc lamps to enable the spectators to follow every movement of the game. The match would have been impossible without the electric light.

Glasgow.—The electric lighting firms in this city report brisk business in installation work. For the present, however, the available current from the Corporation's Waterloo-street central station is all taken up, and further demands can only be met when the new generating plant provided for in the City Electrical Engineer's plans is put down.

Guildford.—The Town Council have consented to the application of the Holloway Electricity Supply Company for permission to apply to the Board of Trade for a Provisional Order, on condition that a clause is inserted giving the Local Authority power to purchase the undertaking within six months after the expiration of a period of ten years from the granting of the Order, and within six months after the expiration of every subsequent period of five years.

Huddersfield.—Extensions are being made to the electric lighting area, and it is contemplated to supply the districts of Marsh and Gledholt.

Leeds.—An attempt is being made by the Leeds Gas Committee to improve the quality of that illuminant. In the mean time many of their customers are adopting the electric light, and private installations are the order of the day.

Leyton.—It has been decided by the Local Board to present a memorial to the Board of Trade for an electric lighting Provisional Order.

Llandudno.—Messrs. Bellis and Kingsland have submitted a scheme to the Improvement Commissioners for the introduction of the electric light into Llandudno. With the sanction of the Commissioners, these gentlemen will take immediate steps to form a local company, and apply to the Board of Trade for a Provisional Order. The subject is to be further considered at a special meeting to be held in January. In the mean time Messrs. Bellis and Kingsland are to set out the terms upon which the proposed company will be prepared to transfer their undertaking after it has been established.

Lynton.—Considerable extensions and alterations are to be made at the electric lighting station here with the object of making room for additional plant.

Manchester Ship Canal.—As evidence that the opening of this canal is likely to materially influence the engineering trade of the district, Messrs. Galloways (Limited), of Manchester, will receive on January 1st, the date of the official opening of the canal, a cargo of 500 tons of steel plates, bars, angles, &c., from Glasgow.

Norwich.—The Town Council have agreed to light the Guildhall and the municipal offices by electricity at a cost of £150.

Sherborne.—Several of the tradesmen at Sherborne, Dorset, are using small electric lamps when on their country rounds. These lamps are similar to those used by the London 'bus companies. The lamps when run down are exchanged at the works of the Sherborne Electric Installation.

Stirling.—At a recent meeting of the Stirling Town Council a letter was read from the Caledonian Electric Supply Company (Limited) asking for the Council's observations upon their proposal to apply for a Provisional Order for lighting the town, and a further letter calling attention to the fact that the Company were still without the Council's remarks on the subject. Subsequently a motion was made that a preliminary meeting of the Council be held in order to obtain the necessary information as to whether they should take up the electric lighting as a Corporation, or hand it over to the Caledonian Company, this meeting to be held on December 26th, and to consider, amongst other business, the report from Mr. Arnot, the Glasgow Corporation's electrical engineer, who has been asked to prepare a report for the Stirling Council's consideration. After a heated discussion the proposal was adopted. There is to be a meeting on the subject on January 8th, when it will be finally decided whether the light is to remain in the hands of the Corporation, or upon what terms the Caledonian Company are to receive the Council's consent to their application for a Provisional Order.

Telephone Extension.—Mr. A. E. Cotterell, the district manager of the National Telephone Company at Birmingham, attended a meeting of Rugby tradespeople and others last week, at which the subject of the extension of the telephone exchange to Rugby was discussed. A committee was formed to ascertain the amount of support likely to be given to the scheme.

Water Power.—The *Rochdale Star* states that some time back Mr. T. Oddy, electrical engineer, of Rochdale, received instructions to prepare specifications for a scheme for the utilisation of water power for electric lighting and power purposes in Southern India, by which it is intended to transmit about 12,000 H.P. to two large towns some distance from the source. The plant is specified to consist of 12 1,000-H.P. turbines, 144 alternators, motors, and dynamos of an average capacity of 250 H.P., and 96 250-H.P. transformers, and will require the erection of two large central station buildings and two transformer stations. The whole scheme, which includes a telephonic installation throughout the district, when completed is to cost about £350,000. The current is to be utilised for power purposes and for lighting a number of cotton, corn, and rice mills, machine shops, &c., *en route*. A scheme similar in character is, according to the same authority, also being reported upon by Mr. Oddy for public authorities in Southern Russia. This project comprehends the transmission of 5,000 H.P. a distance of 93 miles.

Wolverhampton.—The Local Government Board have appointed Mr. T. Codrington, M.I.C.E., to hold an inquiry, at the Town Hall, on Thursday next, into the application by the Town Council to borrow £30,000 for purposes of electric lighting.

Digitized by Google

YALDING (NEAR MAIDSTONE).—A water-power installation is at work at Cheveney, which is giving every satisfaction. The water-wheel drives an Elwell-Parker dynamo, and a battery of 57 large E.P.S. cells provides current for Cheveney Mansion (about a quarter-mile distant), Yalding Vicarage, Riverside House, the Cheveney Institute, the Boys' Brigade Room, &c.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS.

Bedford Electric Light Company (Limited).

The annual general meeting of this Company was held at the offices on Wednesday last week, Sir Henry Mance presiding.

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said the time had arrived when the Town Council must be pressed to give their consent to the Company commencing operations or must undertake the lighting of the town themselves, and be prevented from trifling any longer with the Company. In many places lately the local authorities had handed over the lighting of towns to companies, and that course was becoming more general daily, because in doing so those who had the light paid for it, and the inhabitants of those parts of a town who did not use it, and where it could not be worked at a profit, were not called upon to pay for those who did. When the system was carried out by a Corporation the capital necessary had to be obtained on loan, and repaid, with interest, in annual payments by all the rate payers, whether they used the light or not, but if carried out by a company the capital was an investment, and had not to be refunded, so that interest only has to be paid upon it. When the system was carried out by the Local Authority, even supposing that electric lighting over the whole town might at some distant day pay, it was taxing the present generation for the benefit of their successors. He concluded by moving the adoption of the Directors' report.

Major MOBERLEY seconded the motion, which was carried unanimously.

Mr. George Haynes was re-elected a Director of the Company. Major Moberley was appointed auditor in the place of Mr. William Haynes, who has left the town.

The following is an abstract of the Directors' report :—

"The Directors have made no payment during the past year from the funds of the Company, and have abstained from incurring any liability not absolutely necessary to maintain the Company in a position to act with advantage whenever they deemed a proper opportunity had arisen. It is now more than five years since this Company was registered and fully prepared to commence work, but up to the present time the Corporation have persistently refused their consent to the Company commencing operations. In October, 1890, the Corporation, acting as the Urban Sanitary Authority, obtained an Order to enable them to carry out electric lighting in the town. In July, 1892, they passed a resolution directing the clerk to the authority to apply to the Board of Trade to rescind their Order; but, at a meeting held on the 25th of the same month, the clerk was directed not to make the application until further instructions had been given. On January 19, 1893, the Authority passed a resolution that they should not undertake electric lighting, but should, if practicable, arrange to hand over their Order to a company; and in pursuance of that resolution, and others subsequently passed, advertisements were inserted in various papers, asking various companies and others to submit terms upon which they were prepared to take over the Order. This Company, with others, made proposals for taking over the Order (subject to certain modifications) upon terms which, although highly beneficial to the town and reserving to it a right of purchase at early and reasonable date, would, in the opinion of the Directors, enable the Company to carry out their works with the prospect of a fair return to the shareholders. The Committee appointed by the Authority reported in favour of the proposals made by this Company, and in the report stated that it was the only tender made in accordance with the terms of the advertisements issued, but up to the present time the Authority have not approved nor revised the draft agreement sent to them. The Directors have to remark that if electric lighting were carried out in the town with the extended compulsory area fixed by the present Order, it would necessarily result in a heavy loss to the ratepayers or any Company undertaking it, and they would certainly refuse to accept the heavy responsibilities of the Order without modifications. At the same time there is some doubt whether the Board of Trade have power to reduce the compulsory area without a new Act, or whether, if they have the power, they would do so on the application of the Authority. The Directors, therefore, considered it their duty to give the Authority and the Board of Trade the proper legal notices of their intention to apply for a Provisional Order. The Directors are willing to carry out with the Authority the terms of the draft agreement submitted to them in pursuance of the advertisements issued, which are, in their opinion, liberal to the Authority and fair to the shareholders, but under the circumstances reserve to the Company the right to apply independently for a Provisional Order should the Authority, notwithstanding the trouble and expense their proceedings have entailed upon the Company, refuse to carry out the proposed agreement."

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

BRAYTON OIL ENGINE COMPANY (LIMITED).—This Company was registered on December 22, 1893, with a capital of £80,000, in £5 shares, to acquire a certain invention relating to improvements in hydro-carbon engines, for which letters patent have been granted to George B. Brayton, and to carry on the business of oil-engine manufacturers and dealers, iron and brass founders, machine and engineering tool makers, mechanical engineers, millwrights, metal workers, metallurgists, manufacturing chemists, &c.

R. AND C. HARCOURT AND SON (LIMITED).—This Company has been registered with a capital of £20,000, in 500 £10 "A" Preference, 500 £10 "B" Preference, and 1,000 £1 Ordinary shares, to acquire the business of R. and C. Harcourt and Son, of Birmingham, and to carry on business as brassfounders.

KILMOE COPPER MINES (LIMITED).—This Company was registered on December 21, 1893, with a capital of £30,000, in £1 shares, to acquire, develop, work and turn to account certain copper mines (position not stated), and to carry on the business of a mining, smelting and metallurgical company in all its branches.

J. G. STATTER AND CO. (LIMITED).—This Company was registered on December 21st, with a capital of £20,000, in £10 shares, to acquire and take over as a going concern the business of electrical and mechanical engineers now carried on by John G. Statter, Henry Foote, and Leonard Milne, under the style or firm of "J. G. Statter and Co.," at 68, Victoria-street, Westminster, and Millwall, both in the County of London, with a view to such acquisition, to enter into and carry into effect an agreement already prepared and expressed to be made between the three vendors of the one part, and John H. Ward (for the Company) of the other part, and to carry on the business of electricians, electrical, mechanical, and general engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of, and dealers in, all apparatus and things required for, or connected with, the generation, distribution, supply, accumulation, and employment of electricity.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended December 24th were £950, as against £926 for the corresponding period of last year, being a decrease of £24. The total receipts for the half-year amount to £20,987, as against £20,820 for the corresponding period of 1892, an increase of £167.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—Interest on Coupon No. 4 of First and Second Mortgage Debentures will be payable at the Commercial Bank of Scotland (Limited), 62, Lombard-street, London, on and after January 1, 1894.

ROBEY AND CO. (LIMITED).—Under this title, we are informed that Messrs. Robey and Co., the well-known engineers, of the Globe Works, Lincoln, have converted their business into a limited liability company, with an authorised share capital of £300,000 in Preference and Ordinary shares, £272,710 of which are taken by the partners and holders of capital in the old firm, no issue of any of the Company's share capital having been offered to the public. In addition to the above capital of £300,000, there will be an issue of £125,000 Four and a-Quarter per Cent. Debentures, making a total capital of £425,000. This change has been made in consequence of the deaths of partners, and to facilitate family arrangements, leaving the present management of the business unaltered.

STOCK EXCHANGE NOTICES.—Application has been made to the Committee to appoint a settling day in and to grant a quotation to the further

Digitized by Google

issue of 20,000 Six per Cent. Cumulative Preference Shares, Nos. 20,001 to 40,000, of the City of London Electric Lighting Company (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended December 22nd (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £3,446.

WESTERN UNION TELEGRAPH COMPANY.—A quarterly dividend of 1¼ per cent. has been declared by the directors.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 816.—Vol. XXXII. FRIDAY, JANUARY 5, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The Companionship of the Bath conferred upon Mr. W. H. Preece on New Year's Day is a well-deserved and by no means extravagant recognition of a life-long connection with telegraphy and of nearly a quarter of a century spent in the service of the State. Unlike the majority of our public officials, Mr. Preece has, indeed, been much before the world as a vigorous advocate of electric lighting, as President of the Institution of Electrical Engineers, at British Association meetings, at exhibitions and similar gatherings; he has also made many contributions to scientific literature. But these activities have merely served as so many outlets for an energetic mind. The real work of Mr. Preece's life has been the perfecting of the electrical details of the telegraph system of the United Kingdom, of which all true Britons are in their hearts not a little proud. For his services to this State Department alone Mr. Preece has well earned the distinction now conferred upon him, and we congratulate him upon the fact that, in this respect at least, the State has not been unmindful of its obligations.

We have to express our thanks to the secretaries and engineers of electric supply companies and corporations for the response which they have made to our annual request for statistics. Greatly as our tables have grown in size this year, we are glad to find that they are well filled. Blank spaces are rare, and only two provincial companies of small importance have failed to revise the particulars printed last year. We have endeavoured to lighten the labours of our correspondents by omitting four columns, viz., the maximum load observed, the voltage at the lamps, the voltage at the station, and the number and type of meters. These are interesting in their way, but we are well aware that there is no limit to the number of questions that might be proposed, or the ingenuity of the analyses which might be obtained by dividing one column by another. Those who want to know the number of watts expended per square metre of district may easily satisfy themselves. We have specified the exact intention of some of the columns more clearly than on previous occasions. "Plant capacity" we defined as the aggregate 8-c.p. lamp capacity of the station if every dynamo in the station (inclusive of any so-called "reserve" machines) were running at full load, no allowance being made for C^2R losses. The total length of feeders, separate cables and strips of copper would not give a fair idea of the business of a supply company, nor would the miles of streets in which mains are laid be more accurate, since it frequently happens that a main is laid down one side of a street only. We have therefore asked for "the length in miles of house frontage or pavement along which distributing mains are laid." In another column we give a graphic representation of the growth of electric lighting in London and in the provinces.

Complaining of a recent leading article, in which his name was mentioned, Mr. W. L. Madgen alludes to but does not define "destructive criticism." If we had suggested that the Institution of Electrical Engineers was effete or useless, that it was impeding the advance of science, injuring the profession, or hindering trade; and if, besides this, we had advocated some reactionary movement, we would admit the impeachment. But, on the contrary, we rather deprecated a radical attack on the constitution of the Council; we remarked upon its lack of spontaneous action with regard to wiring rules, the standardising laboratory, and nomenclature. We called attention to an apparently simple method of largely increasing the value of the discussions, one that seems only to require a little firmness on the part of the executive; we recorded with satisfaction the foundation of a building fund; and, finally, we urged that some qualifications should be exacted of the candidates for associateship, for the purpose of raising the status and maintaining the *prestige* of the Institution. Every suggestion that we made was for its welfare and to increase its usefulness. Is this destructive criticism? Our correspondent seems to have mistaken a little plain speaking for "an example of the destructive order of criticism." It must be remembered that the members of the Institution have no voice in the election of the Council. There may be objections to this in theory, but it has become the accepted procedure of most scientific societies. We do not venture to object to it, but it excuses a little free criticism of such details as those on which we have commented. Mr. Madgen thinks otherwise, and prefers private action among members. Anything that will tend to the welfare of the Institution will be welcomed by us.

We print this week an abstract of an article by Mr. Kennelly on the fall of voltage which occurs in long lines when traversed by alternating currents. The results of the investigation there described have an important bearing on the problem of the transmission of power over long distances.

Digitized by Google

Wherever this problem has been attacked high potentials have invariably been adopted, in order to avoid excessive waste in the leads. Mr. KENNELLY's article, however, shows very clearly that unless these high potentials are used the waste in the leads may be very much greater than has been hitherto suspected, owing to the fact that induction in the circuit lowers the power factor, and thus renders it necessary for a larger current to flow in order to supply the requisite amount of power. From the tables of numbers given by Mr. KENNELLY it appears that, if we compare two circuits each of 20 miles in length, the first transmitting power at a potential of 10,000 volts, and the second at 2,000 volts, in the former case the product of volts and amperes will only be about 10 per cent. greater than the number of watts transmitted, while, in the latter case the product will be double the number of watts. This means that the current in the latter case is twice as great as it would be if the line were used to transmit, by means of steady currents, the same amount of power at the same potential, and the waste of power in the leads would, of course, be four times as great. By raising the potential of transmission, the capacity effect of the line is increased, while the self-induction effect is unchanged, and, as these effects oppose each other, and are nearly equal in the case considered, the high potential system is almost free from induction troubles. The investigation shows, however, that the capacity and self-induction effects must be carefully considered in any scheme for the transmission of power to a great distance, for the capacity per mile which Mr. KENNELLY has assumed in his conductors, is no more than any two leads possess when placed at an ordinary distance from one another. Probably these effects will be negligible in the leads to be used at Niagara owing to the low frequency adopted for the current.

THE letter from Messrs. BENNETT and DRUCE, which we print with some reluctance this week, displays strange ignorance both of the professional conduct of certain members of the Council of the Institution of Electrical Engineers, and of the action of the London Chamber of Commerce. To accuse these members of allowing "their conduct at the Council to be influenced by their retainers," even insensibly, is an unwarranted insinuation. A professional expert, even with a general and permanent retainer, would be unworthy of office if he allowed himself to be thus influenced. We cannot agree with our correspondents that a discussion in the technical Press is the proper way to deal with draft regulations of the Board of Trade. When they suggest that "the matter seems to have escaped notice," and speak of "the indifference displayed by the electrical profession in the matter," they are evidently not aware that a special committee of the Electrical Trades Section of the London Chamber of Commerce are actively considering these draft rules. It is highly improbable, if the draft be referred to the Council of the Institution of Electrical Engineers, that a committee with only two practical engineers will be appointed to discuss it, as was the case on a former occasion. We agree that the draft is at variance in several respects with the report of the Joint Committee, especially in Rule No. 14; the Committee of the London Chamber of Commerce have, discovered this long ago It should, moreover, be noted that neither the "line" nor the "return" are mentioned, but only the "feeders." The trouble at Leeds was with the line and the return.

Obituary.—Mr. George H. Babcock, the inventor of the Babcock and Wilcox boiler, died at his home in Plainfield (N.J.), on December 16th, aged 62.

The New Caledonia Cable.—In the first three weeks after its opening to the public (October 19th) the New Caledonia cable transmitted a grand total of 90 messages!

Ealing.—The Local Government Board have given their sanction to the raising by the Local Board of a loan of £25,000 for purposes of electric lighting within their district.

A Proposed New Cable.—The French telegraph authorities are about to invite tenders for a cable connecting Madagascar and Reunion with the telegraph system of the world.

Central London Railway.—The Central London Railway Company have deposited a Bill asking for an extension of time for the completion of their undertaking until the next century.

The Anglo-American Telegraph Company and the Compagnie du Télégraphe de Paris à New York.—The action pending between these two Companies came before the Courts as announced last week, but the hearing was postponed for a month.

Bray.—At a meeting of the Township Commissioners on Monday last the Electric Light Committee recommended that the Town Clerk should be authorised to enter into necessary correspondence with electric light contractors for purchase of plant, &c. The report was adopted.

Berlin-Cologne Telephone Trunk Wire.—The telephone trunk wire between Berlin and Cologne (300 miles) is now open to the public. Three minutes' conversation costs one mark. Urgent messages, which are to take precedence of ordinary ones, are charged for at treble rates.

Society of Arts.—The ordinary meetings of this Society recommence on Wednesday, the 17th inst. On February 14th Prof. Henry Robinson will read a Paper on "The St. Pancras Electric Light Installation," and on February 21st Mr. W. H. Preece, C B., will read a Paper on "Electric Signalling Without Wires."

Railway Station Lighting.—At several of the large stations of the Bavarian railroads electric light plants have been established recently by the management, which reports not only a much-improved illumination but an important economy. The cost at Bamburg, Nuremberg, Ratisbon and Würzburg shows a saving of 44, 40, 54 and 26 per cent. respectively over gas.

Personal.—Mr. Angelo Fahie, of 9, Westland-row, Dublin, has been appointed to the Commission of the Peace for the city of Dublin.—Mr. Haydn T. Harrison has resigned his position as manager of the Testing and Standardizing Department of the Electrical Standardizing, Testing and Training Institution, Charing Cross-road, W.C., and has entered into partnership with Mr. N. F. Nalder.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	October 25th, 1893.
Cayenne-Vizeu	November 25th, 1893.
Lagos-Brass	December 4th, 1893.
San Domingo-Martinique	December 10th, 1893.
Haiphong-Hongkong	December 11th, 1893.
Garachico-Santa Cruz de Palma	December 27th, 1893.

Patents in 1893.—According to information derived from an official source, the number of patents applied for at the Patent Office during the year 1893 was 25,102, a number exceeding any previously recorded in a single year. In 1892, however, the number reached 24,166. There has been a progressive increase in the applications every year since 1885, from 16,011 to the figure given above.

An Electric Traction Prize.—The Metropolitan Traction Company, of New York, has offered a prize of $50,000 to any inventor who before March will bring forward a system that shall "approximate the trolley as a standard of economy in operation but shall be without the features objectionable to the public." The Company has invited the State Railroad Commissioners to be the judges.

Geneva.—According to the report which has recently been issued by the Compagnie de l'Industrie Électrique, of Geneva, the number of consumers on the continuous-current mains of their station was 501, representing 9,996 lamps; and on the alternate-current mains 66 consumers using 1,017 lamps. The report is made up to the end of last March. The available power on the continuous-current mains is 950 H.P., and on the alternate-current mains 250 H.P.

Sunderland.—The Highways Committee of the Town Council have for some time had under consideration the supply of the electric light in the borough; and, as reported in our last issue, provisionally accepted tenders for the work, amounting to £15,074, as against the estimated expenditure of £21,000. At their meeting last Wednesday week the Council confirmed the acceptance of the tenders, and granted the Committee permission to secure a loan not exceeding £25,000 for carrying out the whole scheme.

Northern Society of Electrical Engineers.—We have received from the Secretary the following complete list of officers elected at the first general meeting of this Society:—*President:* Dr. John Hopkinson. *Vice-Presidents:* Mr. Henry Edmunds, Mr. W. P. J. Fawcus, Mr. G. E. Preece. *Council:* Dr. Edward Hopkinson, Mr. J. V. Swindells, Mr. A. Eckstein, Mr. G. W. Lowcock, Mr. E. A. Claremont, Mr. Alexander Marr, Mr. G. S. Corlett, Mr. W. C. Mountain, Mr. J. H. Rider, Mr. J. Taylor, Mr. H. Wooler, Mr. C. S. Northcote.

Accident on H.M.S. "Resolution."—At a further inquiry into the recent explosion on board the "Resolution," at Devonport, the primary cause of the accident was ascertained. Part of the mechanism of the evaporator consists, it seems, of a quantity of zinc slabs and copper pipes; the salt water to be distilled caused electro-chemical action to take place, and it was due to the accumulation of hydrogen and oxygen thus liberated that the explosion occurred. The evaporator is fitted with a safety-valve, which, if opened by hand, would have allowed the hydrogen to escape.

Patents Expiring this Year.—The following are some of the more important electrical patents expiring this year, if not already dropped:—

Dated 1880.	No.	Name.	Subject of Patent.
Jan. 2	18	J. W. Swan......	"Running on the pump."
Jan. 20	250	J. W. Swan	Parchmentised paper filament.
Jan. 23	315	W. R. Lake......	Thomson-Houston dynamo.
Feb. 10	578	T. A. Edison ...	Lampholders.
Apr. 5	1,392	W. R. Lake......	Maxim dynamo.
Apr. 6	1,397	C. D. Abel	Pilsen lamp.
Sep. 16	3,765	E. C. Brewer ...	Edison's bamboo filament.
Sep. 24	3,880	P. Jensen	Edison's feeder system.
Nov. 27	4,933	J. W. Swan......	Parchmentised cotton filament.

The Hull Corporation and Electric Traction.—At a recent meeting of the Electric Lighting Committee of the Hull Corporation a report was presented respecting the application of electricity as the motive power for the tram service. The report stated that electricity could be applied, and it was resolved to appoint a small sub-committee to watch the employment of electricity in this direction. A resolution was also passed asking the Town Clerk to insert a clause in any agreement with a new tramway company binding such company to use the electricity supplied by the Corporation as the motive power.

The Azores Cable.—The following extract from a letter written by a cable man in the Azores is rather amusing:—"The people at Pico said that the cable was the cause of the cyclone, but as it saved them from starving, by bringing the milho at once, they don't consider it such witchcraft as they did at first. It is a fact, though, that the fishermen have said that the 'talking' in the cables has frightened the fish away! People in Pico would not have the land-line insulators on their houses because of this same 'talking.' I have been told that if I had been here a quarter of a century earlier I should have stood a chance of being burnt, and should have figured in the annals of electricity as a martyr to the science."

The Dying-out of Alternating-Current Waves.—In a recent number of the *Electrical Engineer* of New York, Mr. A. E. Kennelly discusses the question of the final shape of an alternate-current wave after passage through a succession of induction coils. Briefly, Mr. Kennelly's statement is that coreless induction coils would transmit an initial sinusoidal wave through an indefinitely long series, unchanged in type. They would also sift an initially non-sinusoidal wave down to a sinusoid, so that practically the conditions might then be closely represented by a sinusoidal generator of reduced amplitude brought into operation further along the line, beyond the principal sphere of shifting action. With iron-core transformers there would broadly be a tendency for the sinusoid to survive.

Battersea Polytechnic Institute.—The classes at this Institute commenced yesterday. The prospectus offers no less than 54 classes, and of these we hope that a large number will be actually started. The nature of the instruction appears to resemble that of the trade classes at the Finsbury Technical College. Many of the classes will prepare for the examinations of the Science and Art Department, and the City and Guilds of London Institute; all students attending such classes are required to undergo the examination. With the exception of special classes for teachers, most of the instruction is given in the evening. The fees for the mathematical courses are specially low, in order to encourage attendance. The following courses are conducted by Dr. W. E. Sumpner:—Magnetism and electricity and laboratory work, technical electricity and laboratory work, for the electrical engineering department of the trade and commercial classes; and sound, light, and heat, for the special classes for teachers. Mr. A. E. Sillar takes a practical class in electrical wiring and house fitting.

Liverpool Overhead Railway.—The Liverpool Overhead Railway, which was started for traffic in March last, has now been taken over from the contractors, the Electric Construction Company. The contractors were under an obligation to work the line for two years from the date of opening at a fixed rate of 4d. per train mile, but we understand the working has been so satisfactory that the railway company has decided to take over the line as from 1st inst., and the Electric Construction Company are relieved from all responsibility of the working and maintenance. The Railway Company contemplate putting into execution the powers they have of creating no less than four new stations at the north end of the line. The Company are also proceeding apace with the extension of the line to Seaforth, where a very fine station is to be built. This extension means about an extra quarter of a mile of new work, and involves the erection of about 20 new spans, one of which is 85ft. in width, and crosses the Lancashire and Yorkshire goods yard. About 15 of the new spans are already erected. Several improved carriages are also to be constructed.

The Multiphase at Budapest.—The multiphase installation carried out at Budapest by Messrs. Schukert and Co., of Nürnberg, for the Budapest Gas Company, has now been in operation for two months. The first plant consists of two 150-H.P. machines, which, together with a battery of accumulators, capable of discharging at the rate of 500 amperes, and having a capacity of 3,000 ampere-hours, are sufficient to supply 6,000 lamps. It is expected that plant sufficient for 15,000 lamps will be laid down and come into operation by February, and the great demand has already induced the Directors of the Gas Company to consider the construction of two sub-stations and the extension of the existing central station. So far as we know, the Budapest system is unique, consisting, as it does, in the transmission of multiphase currents of 25 ∾, at a pressure of 2,000 volts, and its tranformation into continuous currents for the purpose of distribution.——We also learn that the Budapest Tramway Company has decided to extend the use of electricity to its entire system.

Storage Batteries in Telegraph Work.—A recent issue of the *Electrical Engineer* of New York contains a description of the storage battery plant at the office of the Postal Telegraph Cable Company, at Baltimore. This is the first telegraph office in the United States to adopt storage batteries exclusively for the transaction of its business. As one end of a battery used on telegraph lines must be connected to the earth, it was found impracticable to charge the batteries direct from the street mains and at the same time use the batteries for telegraph work. To obviate the necessity of changing the circuits and using extra sets of batteries, a motor-generator was adopted for supplying current to the battery. In this way the street mains are entirely insulated from the charging circuit and the battery can be recharged and used at the same time. Although the voltage of one storage cell is only equivalent to that of two Daniell cells, it is found that where the working conditions are similar to those in the Baltimore office, one storage cell will replace five or more primary cells of the type now generally used in America. The plant at Baltimore consists of 500 30-ampere-hour "Donaldson-Macrae" cells. A Daniell cell in constant operation on a quadruplex circuit gives, says our New York contemporary, an average current of about $\frac{1}{10}$th ampere, or 875 watt-hours per annum, and costs to maintain, at the very lowest estimate, $1.10. The same number of watt-hours, if furnished by the electric light companies of Baltimore, would cost nine cents.

A Simple Method of Investigating the Conducting Power of Dielectric Liquids.—In recent times, says Herr K. R. Koch, in *Wiedemann's Annalen*, many investigations have been made as to the coexistence of dielectric power and electrical conductivity. If it be assumed that electrical conductivity in dielectric liquids is of the nature of electrolysis, we must look for galvanic polarisation in two electrodes inserted in it and connected with a galvanic battery. A capillary electrometer, in which the electrolyte is the liquid itself to be investigated, may be made so sensitive that the existence of a polarisation, and therewith of electrolytic conductivity, may be demonstrated. An ordinary Lippmann's capillary electrometer could not be used for this purpose ; Dewar's form is much more sensitive. This consists of a horizontal tube about 1mm. bore, connected on each side with mercury cups ; the mass of mercury in the tube is separated by a drop of dilute sulphuric acid, if the instrument is to be used in the ordinary way for measuring electrolytic forces ; in the present case the dilute acid was replaced by a drop of the substance to be investigated. If, now the two mercury cups are connected with the poles of a battery, the drops move one way or the other, according to the direction of the current, if the liquid conducts electrolytically, and thus when polarisation takes place at the opposite surfaces of the mercury. With these badly-conducting liquids the drop should not exceed ½mm. in length. Investigated in this way, all dielectric liquids, without exception, exhibit polarisation, always in the direction of an increasing surface-tension at the kathode due to polarisation. It is, however, probable that this phenomenon, in the case of benzole, for instance, is due to the presence of impurity.

Repairing Glow Lamps.—Judge Colt, of the United States Circuit Court of Massachusetts, says the *Electrical World*, handed down an opinion on December 13th, granting an injunction against the Davis Electrical Works, Springfield, Mass., restraining the latter from repairing lamps under the Edison patent by substituting a new filament. The Court states that the process of repairing consists in first breaking off the tip of the glass bulb of the lamp and reaming out a hole about one-half inch in diameter. The broken filament is then removed. The new filament, having its ends cemented into platinum sleeves, is then inserted into the glass chamber, the sleeves being pushed down over the two platinum leading-in wires and compressed upon them. A tube of glass made into the shape of a funnel is heated and placed over the hole in the lamp chamber. This tube is fused into the open end of the bulb, which brings it into the condition of the ordinary lamp bulb just prior to exhaustion. The air is then exhausted and the bulb sealed. It is evident, the Court decides, that this operation covers many of the constructive features of the ordinary lamp, whose claim consists of four elements : a carbon filament, a receiver made entirely of glass, conductors passing through the glass, and a receiver from which the air is exhausted. It is apparent, the decision says, that the defendants by substituting a new filament, making over the glass receiver, and exhausting the air from such receiver, produce a lamp in which all the elements but one (the leading-in wires) of the patented combination, are used either in a new or reconstructed form. The lamp thus produced is substantially a new lamp, and its voltage may be higher or lower than the old one. From the very nature of the Edison invention, the Court does not see how the glass bulb can be opened and a new filament inserted without making essentially a new lamp.

Brighton.—The following is an abstract of the report presented by the Electric Lighting Committee of the Brighton Corporation at yesterday's meeting of the Town Council :—A little more than two years ago a proposal to buy up the Brighton and Hove Electric Lighting Company by the Town Council for £7,000 was rejected by the Council, but two months ago negotiations were reopened by the Receiver and Manager, appointed on behalf of the debenture-holders of the Company. After some haggling, the contending parties came to the following agreement :—The Corporation to purchase the Company's undertaking for the sum of £5,000, one-half of which sum to be paid on September 30, 1894, and the other half to be paid within one month of it being certified to the Corporation that the overhead wires, posts, and apparatus belonging to the Company have been removed to the satisfaction of the Borough Surveyor ; the Company to continue to supply their own customers until September 30th, bearing all the expense and receiving all the revenue. As a considerable extension of the Brighton Corporation's present system will be necessary, if this agreement is ratified by the Town Council, the Committee instructed Mr. Arthur Wright to report as to the probable cost. For the purpose of the estimate, Mr. Wright has divided the 232 consumers at present connected to the Company's mains into three classes, viz., (1) consumers in streets in which the Corporation mains are laid, (2) in the Corporation's area of supply but where mains have not yet been laid, (3) outside the area of supply. The following table gives particulars of number of consumers, probable income, &c. :—

—	Consumers.	Lamps.	Units consumed.	Annual income.
Class 1	•162	7,159	122,920	£3,073
Class 2	43	1,113	19,080	477
Class 3	27	1,393	12,000	300
Total	232	9,665	154,000	£3,850

The total capital outlay is estimated by Mr. Wright at £19,227, the total annual cost of supplying the whole of the Company's customers is put down at £3,265, and the total annual revenue is put down at £3,850, leaving an estimated profit of £585, no allowance being made for the sum of £5,000, which it is proposed to give for the Brighton Company's business. The Electric Lighting Committee having also come to the conclusion that the time has arrived for providing the Preston district with the electric light, Mr. Wright also reported on that point, recommending the district to be supplied from the present Corporation station, but on the high-pressure alternate-current house-transformer system. The Committee, therefore, ask for power to borrow £35,000, the items of which are as below :—

1. Purchase money payable to the Company	£5,000
2. Additional mains and plant for supplying Company's customers	19,227
3. For plant and mains for supplying the Preston district	4,290
4. For laying on new house services and purchasing additional meters............	6,483
	£35,000

At yesterday's meeting of the Town Council some criticism was passed on the figure at which the Company's business was to be purchased, but eventually the report was adopted unanimously.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 136.)

Storage of Energy.—Energy storage constitutes a most important mechanical and economic question in the design of motive power plant. The fact that energy can be retained for a long or short period in a state of reserve, both in a kinetic and in a potential form, is taken advantage of in several ways in machinery problems. Storage occurs both by accident and by design. Accidental storage is due to the fact that every moving piece of machinery will absorb or liberate an amount of energy proportional to its change of motion. This exerts a modifying influence, of course, upon the flow of energy through the chain of mechanical parts, as well as upon the distribution of stresses in those parts. Intentional storage occurs where a capacious reservoir is placed in the path of the energy flow, with the deliberate purpose of causing some or all of the energy to remain for a certain time in the reservoir instead of passing on to the dynamo. The general action of energy storage is illustrated in Fig. 6. Let the axis y represent the power or the driving force, and the axis x the time or the distance covered by the driving force respectively; then the area subtended by any curve on these axes will represent an amount of energy transmitted, or of work done. Now, let it be supposed that at any point in the path of the energy flow from the initial source to the dynamo there is a reservoir or store inserted. We may consider two cases which arise in practice: the first, in which the energy is supplied to this point at an irregular rate, such as is shown in curve (*a*), and is required to be drawn off at a regular rate, such as shown in curve (*b*); the second, where the conditions are reversed, the energy being given to the point regularly, but requiring to be taken away at an irregular rate. In the first case the power and the stresses in the mechanical parts nearer to the source than the reservoir will follow the irregular curve (*a*), and will at some times be very much above the average, as they will at other times be very much below that average. And the mechanical parts further from the source than the reservoir will be subjected to an even and steady state of stress and power transmission, as indicated by the curve (*b*). The distribution of power and of stress is reversed in the second case. In both cases there is a certain amount of energy which alternately flows into and out of the reservoir; flowing into it when the supply is greater than the discharge, and out of it when the discharge is greater than the supply. The amount of this fluctuating energy will determine the capacity which the reservoir should have.

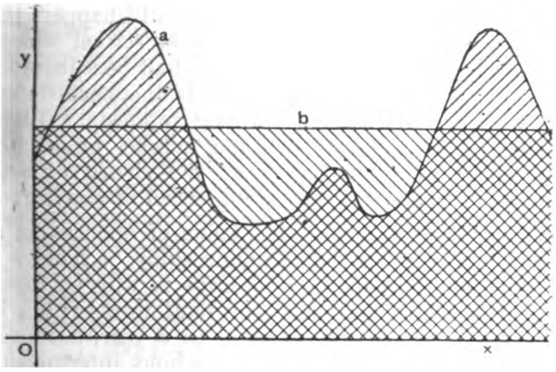

FIG. 6.

In relation to the production of mechanical motive power we may consider three forms of energy storage:—

(1) *Source Storage.*—In which the initial source of energy is conserved.

(2) *Transit Storage.*—In which the energy is stored at some point in its transmission through the chain of machinery from the source to the dynamo.

(3) *Supply Storage.*—In which the energy at its ultimate stage in the dynamo is passed into a reservoir at a steady rate.

Source storage is not always possible. Wind power is an instance in which it is impossible to conserve the initial source of energy; we must take the wind as it comes. In the water power of a small stream we find source storage not only possible, but often necessary; and with tidal motors it is always necessary. Coal stores represent a form of this class of storage. The two chief reasons for source storage are: (1) actual or liable irregularity, or complete failure, of the supply, the demand being regular or at a different rate: and (2) small, steady rate of supply, with a demand which is either continuously or intermittently very much in excess of this supply. Transit storage may be considered to occur when there is storage of energy after it has been prepared by artificial mechanism and before it has been passed into the dynamo. In Fig. 7, let A represent the source of energy, and B the dynamo to which it is being supplied. The line A B is taken to represent the chain of mechanical parts through which the energy is passed. A store, or reservoir, C, is placed somewhere in this line, so as to intercept the whole or part of the energy in its transit from A to B. In the case marked (*a*) the store transforms the flow of energy from an irregular into a regular rate, so that the mechanism in the line A C will be subjected to irregular actions as curve (*a*) in Fig. 6 while the mechanism in the line C B will be subjected to regular or steady actions. In the case marked (*b*) the converse conditions will hold; the first part of the chain of mechanism will be steadily acted on, while the second part will be subjected to variable action. Now, let it be required that each separate part of the chain of mechanism, A B, shall transmit the energy with as little stress, and at as small a maximum rate, as possible. These requirements will arise in practice on account of the fact that the size, weight, durability, &c., of the several parts, and, therefore, their prime and working costs, will depend directly upon the amounts of the maximum stresses and the maximum power which each will have to support. It will be well understood, then, that in practice we require to place the transit store or reservoir in such a position, and to have it so designed, that as much as possible of the line, A B, shall be subjected to as small as possible maximum of stress or power. Now, it is evident that the maximum will be as small as possible when the flow of energy is steady and regular, for then the maximum will be neither greater nor less than the mean value. The required conditions are therefore obtained when it has been arranged that as much as possible of the line A B shall transmit energy at a constant and regular rate. And in order to arrive at this result it will be necessary to place the store close to A in the first case, and close to B in the second case. There arises, then, the following general principle in regard to the use of an energy store for the equalisation of the stresses and power in machinery:—*In any arrangement of mechanical or other parts for the transmission of energy, the energy entering the arrangement at an irregular or fluctuating rate and leaving it at a regular rate, or* vice versâ, *the successive parts will be subjected to the least straining action, and will be required to transmit the least power if the store or reservoir, for transforming the rate from one value to the other, is placed at the least possible distance from the actual seat of the fluctuation.* In the subsequent sections of this work it will be seen that this principle is of vital importance, as

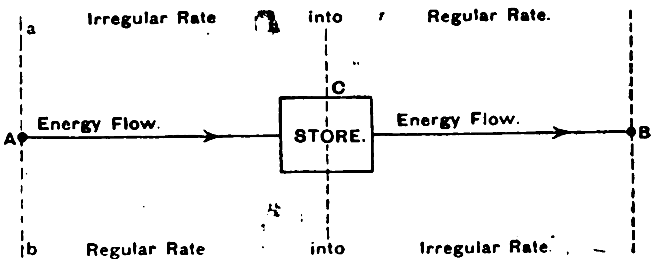

FIG. 7.

Digitized by Google

affecting the design of machinery. As examples of transit-storage we may mention flywheels, hot water in boilers, and hydraulic accumulators. The last form of storage, namely, supply-storage, only affects the motive power plant indirectly, as it takes place beyond the point at which the energy is supplied to the dynamo. Nevertheless, its influence upon the mechanical design of that plant is very important; for where the dynamo is employed in pouring energy at a steady rate into a form of reservoir (such as that energy-reservoir called a secondary battery) it will be evident that the load-diagram of the dynamo, and of the mechanical parts which transmit power to the dynamo, will be very different from the load-diagram of a dynamo supplying power to a fluctuating demand. With this form of energy storage, in so far as it is electrical or chemical and not mechanical, we shall here have nothing to do; but with its effect upon the engines and the accessory details, some future articles must be concerned. Electrical engineers will do well, however, to apply to supply-storage, whether on lighting or traction circuits, those principles which we have already enunciated in regard to transit storage; for it is equally true in this case as in that, that the most advantageous and efficient arrangement tends to be attained the more closely the store is placed to the seat of fluctuation of the power.

A Statement of the Problem.

The study of motive power and gearing for electrical engineering may be regarded as one great problem, with which every engineer is confronted when he commences to make his plans and designs for an electric-power plant. And, as has already been said, it is in the form of a single problem that this study is made in the present series. Broadly speaking, the main problem may be stated thus:—*What are the best provisions which may be made for utilising the available energy for the performance of useful work and the production of a paying revenue?*

No final answer can be given to such a question in any general treatise; for there are many determining influences which are purely local, and which can only be taken into account when the local conditions are known, or, at most, when the relative local values of several proposed localities have been compared. For example, it would be impossible to give in a general treatise such information as would make it certain, without local inquiries, that at the little town of Waterville it would be better to use a water-power engine than a steam engine; or that at the village of Riverside it would pay to use a condensing plant rather than a non-condensing one. Yet, while this is so, it is to be noticed, firstly, that no proper estimate can be set upon the local advantages or disadvantages unless the general merits and demerits of each mode of producing motive power are thoroughly understood; and secondly, that in the majority of cases the local considerations are of lesser importance than the more general ones which may be rigidly defined in a standard treatise. All that can be done, therefore, is to perform the part of a guide to the engineer, to help him in affixing proper values to the various considerations which come before him. And the work of doing this is not unimportant.

Details of the Problem.—For the problem is by no means a simple one, but consists of a great number of inter-dependent details; and it has often to be approached from two or more points of view. In the first place there must be a comparison of the mechanical and electrical aspects of the problem. The questions of motive power must be influenced by the character of the electrical work which has to be done by the plant; as, for example, whether the power is to be used for electric lighting and general power distribution, or for electric traction, and as to the variation of load from hour to hour, or from moment to moment, which may be expected. It is impossible to have successful mechanical design where there is not a close acquaintance with the electrical duties which will be imposed upon the plant, and of the effect of these upon the relative merits of different forms of plant design. On the other hand, it is almost as important that the electrical engineer shall be cognisant of the peculiarities of each form of motive power, in order that he may, wherever possible, endeavour to modify the character of the electrical loads in such a manner as best to adapt them to the working of the mechanical plant. In other words, the electrical engineer who is familiar with the behaviour of various types and arrangements of engines in a power station, under various conditions of load distribution, will be in a position to avail himself of every opportunity to so distribute and modify the load as to get the highest economy, and the greatest revenue on a minimum capital, out of his plant. We shall presently see in what ways such a modification of the electrical load on the plant may be effected.

From another point of view, the selection of a type of motive power is influenced by the character, both of the local sources of energy and of the area to be supplied with power. The presence of water power in large amounts will always, of course, have a prime influence; but it may happen that even in such cases as this there will be conflicting conditions. Again, the attraction of a cheap site for a power station at the top of a hill may offer advantages in low rent, rates and taxes, but may have a corresponding disadvantage in the increased cost of cartage of fuel to the top of the hill, and possibly in the scarcity of water; while an alternative site on a canal or river side may offer advantages in cheap fuel and abundant water, but may have the electrical disadvantage of being some distance from the centre of the area to be supplied with power, thus necessitating the use of expensive cables or the adoption of a more expensive system of power distribution. Assuming the general type of motive power to have been already decided upon, it will still happen that the precise character of that type will only be settled when it has been decided which of these two sites shall be selected. The ultimate choice of a species of engine is therefore determined by the balance of many conflicting interests. There still remain the questions of the size and number of engines, the distribution of load on these, and the choice of accessory engine details, beside the separate question of gearing.

The Factor of Idleness.—The factor of idleness is a most important coefficient in the economic study of motive power. From the definition of this quantity it will be seen that if we multiply this factor by the total work which can be done by a station or unit of plant in a year, assuming full work to be done by all the engines without intermission, the product will be the idleness of the station or plant, expressed in available but unrealised units of work. It may be found convenient to express the idleness of a plant in horse-power hours. It is to be carefully observed that this factor depends only upon the total capacity of the plant and upon the character of the load diagram. In a station composed of many engines, the idleness of the entire plant is equal to the sum of the idleness of all the separate engines; and by no alteration of the distribution of load among the engines themselves can this quantity be either diminished or increased. Thus, it makes no difference to the total idleness if any given engine is worked for the whole time at half power, or if it is worked for only half the time at full power. Now it will be evident that the idleness of any portion of plant expresses the degree of unproductiveness of the capital invested in it; for, in proportion to the idleness there must be a scarcity of revenue. This question is altogether apart from the question of the efficiency of the plant at various loads, and relates solely to the proportion of the whole time during which the whole capital may be said to be active or productive. There are only two ways in which the idleness of a station or plant may be diminished. If the amount of plant is fixed, the idleness may be reduced by imposing upon it a load which is maintained for a longer time nearer to its maximum value; and the ideal state is where the whole plant is kept at full load for the whole time. If the character of the station load diagram is fixed, the idleness may be reduced by providing a system of energy storage whereby the load may be equalised on the engines throughout the time; provided, of course, that the capital invested in storage plant is not in excess of the capital saved in engine plant. An instance of the former occurs in the efforts which are made by electrical engineers to induce power consumers to take power at cheaper rates during

Digitized by Google

the hours of minimum load; and an instance of the latter occurs in the use of extremely heavy flywheels on the engines of electric traction power stations, or again in the use of secondary batteries on electric power circuits.

(*To be continued.*)

ON THE FALL OF PRESSURE IN LONG LEADS TRAVERSED BY ALTERNATING CURRENTS.*

With short lines any inductive effect which is appreciable is due entirely to electromagnetic action; but when lines are of considerable length the effects of capacity and leakage become of great and, indeed, paramount importance. An approximate method of taking account of these new effects is to consider the capacity and leakage concentrated at one part of the circuit, and to treat these shunts as derived impedance circuits. But this plan is not rigorous, and the extent of its error is left in doubt. The object of Mr. Kennelly's article is to show how the rigorous computation for the fall of pressure in lines of known resistance, inductance, leakage, and capacity, carrying sinuous currents, can be most simply carried out.

Suppose a generating station, A, supplies a consumption point, B, at a distance of L miles or kilometres through two wires in metallic circuit, or through one wire with ground return. At B there are transformers or translating devices operated at a pressure u that it is usual to keep nearly uniform. Under this pressure, at any given load, a certain effective current of i amperes will traverse the apparatus at an angle of lag θ. We assume that the current and lag are experimentally known for the particular apparatus and load. Having then given u, i, and θ at station B, the problem is to determine the corresponding pressure U, and current I at A, or at any intermediate point along the line.

Let r = the resistance of the line in ohms per mile,
l = the inductance " " henrys "
g = the leakage conductance " " mhos "
c = the capacity " " farads "
ω = frequency $\times 2\pi$,
$j = \sqrt{-1}$, and L = length of line in miles.

Then, by considering the problem mathematically in the manner first shown by Mr. O. Heaviside, it can be proved that

$$U = u \cosh Lz + y\,i \sinh Lz. \quad . \quad . \quad . \quad (1)$$

$$\text{and } I = i \cosh Lz + \frac{u}{y} \sinh Lz, \quad . \quad . \quad . \quad (2)$$

$$\text{where } z = \sqrt{(r + jl\omega)(g + jc\omega)} \quad \text{and} \quad y = \sqrt{\frac{r + jl\omega}{g + jc\omega}} \quad . \quad (3)$$

These equations involve plane vectors or the "complex quantities" of algebra, and Mr. Kennelly proceeds to explain some properties of these functions, which are necessary for the solution of the present problem. The original article also contains a full description of a geometrical method of calculating the quantities given in the above equations, illustrated by the complete numerical working of the two problems referred to below. As, however, comparatively few electricians are familiar with the properties of the hyperbolic sines and cosines, or with the manipulation of vector quantities, we refer our mathematical readers to the *Electrical World* of New York for the detailed description of Mr. Kennelly's method, confining ourselves to the statement of the problems studied by him and the results which he obtains.

The first example considered is the following:—

At station B transformers are supplied at a steady pressure of 10,000 volts effective, and at 100 ∿, through two #0 A.W.G. wires of copper in metallic circuit, suspended on high poles at an interaxial distance of 2ft. The resistance of this conductor is 0·508 ohm per mile, the inductance 1·688 millihenrys per mile, the capacity 0·081 microfarad per mile, and the leakage negligible, or the leakage conductance 0 mhos per mile. To find the pressure and current at A, distant twenty miles from B, when a full load of 50 amperes is sustained with a lag of 10deg. at B.

* Abstract of a Paper kindly sent us by Mr. A. E. Kennelly.

This metallic circuit may be divided by the imaginary line O O (Fig. 1) into two halves, each as though independent of the other, and operating with ground return at 5,000 volts. We then have:—

$u = 5{,}000$
$i = 50$
$\theta = -10^\circ$
$r = 0{\cdot}508$
$l = 1{\cdot}688 \times 10^{-3}$ $\therefore$ $l\omega = 1{\cdot}061$
$c = 8{\cdot}1 \times 10^{-8}$ $\therefore$ $c\omega = 5{\cdot}09 \times 10^{-5}$
$\omega = 628{\cdot}3$
$L = 20$

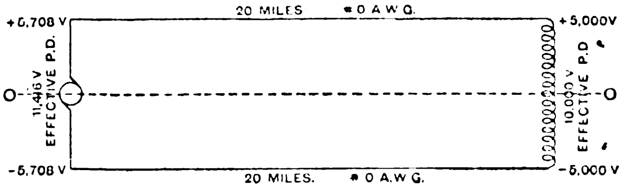

Fig. 1.

By solving equation (1) it is found that the two terms composing the voltage U
re 4,942 volts at a phase angle of 0° 18′,
and 1,173 volts at a phase angle of 54° 31′.

These are shown to combine by vector addition to
5,708 volts at a phase angle of 9° 54′.

Similarly, by applying formula (2), it is shown that the current I consists of two components, the first of which is
49·418 amperes at a phase angle of − 9° 42′,
and the second
5·072 amperes at a phase angle of + 90° 6′.

By summing these components it is found that
I = 48·81 amperes, the phase being − 3° 49′.

The effective pressure at A being represented in Fig. 2 by A C and the effective current by D F, the angle between them

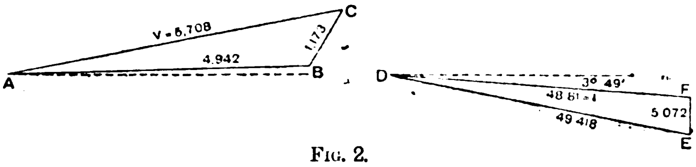

Fig. 2.

is 13deg. 43min., and the energy delivered to the line is I . U . cos 13deg. 43min. = 270·7 kilowatts. The energy absorbed at B is $i \cdot u \cdot \cos$ 10deg., or 246·2 kilowatts on each side of the circuit, and the loss in its transmission 24·5 kilowatts. This loss can only exist as $i^2 r$, the value of which must fall between $(50)^2 \times 10{\cdot}16 = 25{\cdot}4$ and $(48{\cdot}81)^2 \times 10{\cdot}16 = 24{\cdot}20$ kilowatts, the mean being 24·8, confirming the above calculation. The total pressure at A is thus 11,416 volts, and the current 48·81 amperes.

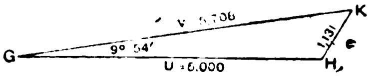

Fig. 3.

The drop on each wire is 708 volts; the drop due to I R on a similar continuous-current conductor would be 496 volts; the impedance factor for these wires being 2·316, the drop would be by magnetic impedance 1,150 volts; the actual drop between far and near ends of one line is shown in Fig 3 to be G K = 1,131 volts; the influence of electrostatic capacity has reduced the drop in the line as measured between line terminals from 1,150 volts to 1,131.

The other example taken by Mr. Kennelly is to suppose that 10,000 volts are maintained at B, and the load entirely removed. In this case the second term disappears from equation (1), and the first term from equation (2), so that we have at once $U = 5{,}000 \times \cosh Lz = 4{,}942$ volts, the phase being 0deg. 18min., and the two terms composing I are respectively

Digitized by Google

6·576 × 10^{-3} and 0·1542, the phase of the former being 12deg. 47min., and that of the latter 77deg. 19min. These combine to 5·073 at a phase of 90deg. 6min. The energy absorbed at A is U . I . cos θ on each wire, or 44 watts. The impedance of a condenser having the same capacity as the line, viz :—1·62 microfarads at 100 ∿ would be 982·3 ohms, making the line current in this case 5,000/982·3 = 5·09 amperes, in practical accordance with the above.

Tables I. and II. illustrate the effect of distance and of pressure upon the drop in lines considered in the foregoing examples. In Table I. the current and pressure are marked off at 10, 20, and 50 miles from B at a supposed full load of 50 amperes, and at no load with 10,000 volts total effective delivery pressure, or 5,000 positive and negative measured from the zero point or load centre. Table II. gives the corresponding figures for 2,000 volts total delivery pressure or 1,000 volts on each side of zero. The drop is in the latter case much too great at full load for the conditions of ordinary practice, but the comparison of the two series shows how much the drop may be reduced in long-distance transmission over such wires by the employment of high pressure with a given current strength ; for the electromagnetic effect is practically unaltered, while the neutralising electrostatic effect is correspondingly increased. At no load the pressure here rises along the line.

THE ELECTRICAL CONCENTRATION OF SULPHURIC ACID.

BY BERTRAM BLOUNT, F.I.C.

Since the publication in *The Electrician* of November 10th last of an account of the investigation by A. H. Bucherer from thermo chemical data of the possibility of electrically concentrating sulphuric acid on an industrial scale, C. Haeussermann and F. Niethammer have described in the *Chemiker Zeitung* certain experiments devised to test the conclusions arrived at by the former investigator on purely theoretical grounds.

In reducing any system of vitriol concentration by electricity devised by a mathematical process to practice, the point that first claims settlement is the decision between the merits of a direct and an alternating current. Hot concentrated sulphuric acid is not a very familiar electrolyte, and but few can foretell its behaviour with any pretension to accuracy. Direct experiment is the only means of filling the gap, and this has now been carried out. A current of 14 amperes and 7 volts sent through a bent platinum wire 30cm. long and 0·47mm. in diameter, dipping into a beaker of sulphuric acid at 60°B, raised the temperature of the acid to 190°C, and caused it to lose about 11 per cent. of its original weight in two and a-half hours, but failed to raise its specific gravity more than to 61°B. The comparatively large loss was due to electrolysis taking place between parts of the wire physically adjacent, but of different potential. The occurrence of electrolysis was also inferred from the separation of sulphur, which then entered into secondary reactions with the hot acid, and the escape of gaseous products of decomposition. A remedy for this state of things was sought in the decrease of the conductivity of the acid relative to that of the wire. This was accomplished by using a wire of the same length (30cm.), but of slightly greater thickness (0·5mm.), and disposing it so that it traversed a horizontal glass tube in a straight line. When the diameter of the glass tube was 27mm. sufficient electrolysis took place to account for a large part of the current, and it was not until the diameter had been reduced to 8mm. that tolerable results were obtained. Even under these conditions, however, the use of a direct current was not sufficiently successful to warrant its continuance.

When an alternating current was resorted to, the electrolytic difficulty nearly disappeared. Thus, working with an alternating current of 14 amperes and 7 volts, Haeussermann and Niethammer succeeded in concentrating sulphuric acid to 65·8°B with a loss of weight of rather less than 20 per cent. The expenditure calculated from this experiment amounted to 1,490 watt-hours for 1 kilo of the concentrated acid. This does not compare very brilliantly with the calculated expenditure, representing, as it does, an efficiency of 25 per cent. It will be remembered that even the theoretical expenditure given in the article in *The Electrician*, already referred to, corresponded with a higher money cost than that of the usual methods of concentration, whence it follows that with an efficiency of 25 per cent. the electrical concentration of sulphuric acid may be relegated to that millennial period when some 90 per cent. of the energy of fuel can be obtained as electrical energy in every day working.

PHENOMENA OF THE TIME-INFINITESIMAL.*

BY PROF. E. L. NICHOLS.

Science consists in the extension of our knowledge of the external universe, and it brings about this extension in great part by reinforcement of our senses. To bring into the field of observation the very distant and the very small are, therefore, regarded as important scientific achievements, and the telescope and the microscope, by means of which this widening of the realm of knowledge has been made, as important implements of research.

As between the study of the infinitely great and the infinitesimally small, whether of space or of time, there is a peculiar value to be attached to the latter, because the only methods which have proved the least fruitful in the analysis of the more complex changes which are going on around us are those which begin with the infinitesimal. We consider an element of mass or of volume, or sometimes merely the element of a surface or line, proceeding then to extend our statements so far as our powers of mathematical expression will permit.

Now the element of time is, of course, purely relative. In certain phenomena the time infinitesimal is so short as compared with any time interval with which we are able to cope experimentally as to be out of reach, just as in special relations the dimensions of the molecule and atom are such that we dare not hope to render these ultimate particles of matter visible even under the microscope. There are periodic phenomena, on the other hand, the periods of which are so great that a lifetime, indeed the entire era covered by history and tradition, affords us a glimpse of but a single time element. Lying between these two there is a great range of phenomena for which the element of time is within our reach. It is by the study of what takes place in such time elements, and the extension of the results thus obtained by analytical processes, that much of our knowledge of physics has been gained.

* Abstract of an address delivered before Section B (Physics) of the American Association for the Advancement of Science, Madison meeting, August 1893.

Digitized by Google

It is to the extension of our powers in the observation of the phenomena of the time interval that we must look in great part for further progress. It has seemed worth while, therefore, to bring together for purposes of comparison some of the methods which have proved fruitful in this respect, and to consider along what line they may be further developed. It is an investigation which will lead us into all departments of science; for phenomena into which the element of time does not enter are unknown.

Since all study of phenomena involves the time element, the consideration of all dynamical problems must begin with the *phenomena* of the *time-infinitesimal*. There are two cases of chief importance:—(1) The study of the time elements of periodic phenomena; (2) the study of beginnings of changes which result from a sudden variation in the condition of equilibrium.

The methods which have been found most useful in the investigation of the phenomena under consideration may be classified as follows:—(1) Visual methods: (*a*) vision by instantaneous exposure, (*b*) vision by periodically interrupted exposure, (*c*) vision by the aid of the revolving mirror. (2) Photographic methods: (*a*) instantaneous exposure of a stationary film, (b) photography by the aid of the revolving mirror, (*c*) continuous exposure of a moving plate, (*d*) successive short time exposure of a moving plate. (3) Indirect graphical and electrical methods.

The inventor of the revolving mirror (Wheatstone) found it possible to study time intervals down to within a millionth of a second (*Philosophical Transactions*, 1834). He obtained a rate of revolution never since greatly exceeded, I think, of 800 revolutions a second. It is evident that he stood at the very threshhold of the discovery of the oscillatory discharge, and that it was merely an accident of the relation of resistance and capacity in the circuits which he employed, which prevented him from observing that important form of the electric spark. That he was fully aware of the wide range of investigations to which the revolving mirror is adapted is also clear. He says in the memoir which Faraday presented for him before the Royal Society in 1834: "But this instrument is not confined to observing merely the intermittedness of electric light; whenever a rapid succession of alterations occurs in an object which does not change its place, they may be separately examined by this means. Vibrating bodies afford many instances for investigation; one among these is perhaps worthy to be mentioned. A flame of hydrogen gas burning in the open air presents a continuous circle in the mirror, but while producing a sound within a glass tube, regular intermissions of intensity are observed, which present a chain-like appearance, and indicate alternate contractions and dilations of the flame corresponding with the sonorous vibrations of the column of air."

In a later paragraph of the same Paper he noted the applicability of the spark in the study of the phenomena of the time-infinitesimal, suggesting a method the importance of which is even now imperfectly appreciated. "The instantaneousness of the light of electricity of high tension affords the means of observing rapidly-changing phenomena during a single instant of their continued action."

In the hands of Foucault ("Recueil des Travaux Scientifiques," Paris, 1878), Michelson (*Proc.* A.A.A.S., 1879, also "Papers of Amer. Ephemeris," Vols. I. and II., 1882), and of Newcomb ("Astro. Papers of Amer. Ephemeris," Vol. II.), the revolving mirror has given us our best determinations of the velocity of light; in those of Feddersen ("Beiträge zur Kenntniss des Electrischen Funkens, 1857"). Also *Pogg. Ann.*, 103, 113, 116 (1859 to 1862), Rood (*Amer. Journal of Science*, Vol. II., 111, p. 160), Trowbridge (*Amer. Journal of Science*, Vol. XLII., 111, p. 223), and Boys (*Phil. Mag.*, Vol. XXX., 111, p. 248), and others, it has made it possible to resolve the oscillatory spark into its elements.

Feddersen's experiments are especially noteworthy because he succeeded (in 1862) (*Pogg. Ann.* 116, p. 132) in photographing the discharge of the Leyden jar, securing an excellent record of the images seen in the revolving mirror. We are apt at the present day to look back to the introduction of the dry plate as the step necessary to the application of photography to the study of fleeting phenomena, but certainly the results obtained by this early investigator, who used the ordinary wet-plate process of his time, are not inferior in definition or in detail to any which have been published in recent years. Feddersen's researches are indeed worthy of all admiration. He used a concave mirror, giving excellent images when driven at a speed of 100 revolutions a second. The velocity was under the regulation to within 2 per cent., and the millionth of a second represented not merely an appreciable distance upon the negative, it was an *easily measurable* quantity.

More than thirty years ago this German physicist stood, as Wheatstone had done nearly half a century before him, in the very gateway of the domain in which such activity has shown itself of late—the domain of electrical resonance. He was not only the discoverer along experimental lines of the oscillatory discharge and the demonstrator of the existence of effects which had already been embodied in the analytical work of Helmholtz, Thomson, and Kirchhoff; he anticipated also many of the discoveries of later investigators, and worked out quantitatively the dependence of the rate of oscillation upon capacity, induction, and resistance. Two of Feddersen's photographs have been brought to general notice by reproduction in the fourth volume of Wiedemann's "Electricität." There is another set which I consider even more significant, showing the increase in the number of oscillations with diminishing resistance.

Another forerunner in the development of the methods which it is my privilege to consider, was Prof. E. W. Blake, of Brown University. His results, too, have become classical; but I refer to them because they are related in ways not always recognised in later work. We are all familiar with his interesting photographs obtained by speaking into the mouthpiece of a Bell telephone (Blake, *Amer. Journal of Science*, Vol. XVI., 3, p. 57), to the diaphragm of which was attached a rocking mirror. Records obtained in a variety of other well-known ways, of some of which I shall have occasion to speak, indicate that these photographs do not give a complete trace of the vibrations which go to make up the articulate utterances by means of which they were excited, but the method is of interest in three particulars:—

(1) It is one of the earliest attempts to substitute photography for vision in the study of the transient phenomena of the sound wave.

(2) It substitutes a moving sensitive plate for the revolving mirror.*

(3) It is a distinct forerunner of the method applied some years later with somewhat better success by Froelich to the analysis of alternate-current phenomena.

Throughout the history of the study of the phenomena of the time-infinitesimal we find the tendency to be to supplant visual methods by methods of photographic record.

In the study of periodic phenomena two distinct methods of investigation have been established. The first of these consists in the isolation of a desired element of the cycle at each repetition for as long a time as may be necessary to obtain a satisfactory record of the existing conditions. By the selection successively of many neighbouring elements, we get in this way at last the data from which to construct a complete diagram of the cycle.

This principle has been most fruitful in enabling us to analyse periodic processes not easily approachable by more direct means. The most notable application has been that which is commonly spoken of as the "method of instantaneous contact," well known to the student of alternating-current phenomena.

It is to Joubert† (1880) that we owe this ingenious adaptation of the device of properly-timed repetitions of instantaneous observations of periodic phenomena (a principle which underlies the phenakistoscope and similar well-known instruments). He made use of it in the study of the changes of potential in the circuit of the alternating-current dynamo, and between the terminals of the Jablochkoff candle.

In the same year the method was discovered independently, and applied to the study of the Brush arc-lighting dynamo by B. F. Thomas.‡ Joubert pointed out the method of using the quadrant electrometer in alternating circuits, also that the galvanometer might be utilised. He discovered the retardation of phase in the current curves of the alternating dynamo, and the peculiar distortion of the curves in the circuit containing an arc lamp, a matter more fully investigated at a later day by Tobey and Walbridge.‖ Thomas during this first period in the history of the Joubert method used a ballistic galvanometer and condenser.

The periodic phenomena of the alternating-current circuit have been among the most important to which the study of the time-element has been applied, and it is to the method of instantaneous contacts that we owe much of the progress of the last thirteen years. It is interesting to note the extension of this method in the study of a variety of allied phenomena. After the publication of Joubert's Papers the method seems to have come into common use in the physical laboratories, particularly in the exploration of the fields of continuous-current dynamos and motors.

In 1888 it was applied by Duncan, Hutchinson, and Wilkes ("Experiments on Induction Coils," *Electrical World*, Vol. II., p. 160, 1888) to the study of induction coils and transformers. To

* Stein, in a Paper cited by Prof. Blake (*Pogg. Ann.* 159, 1876), describes a similar device, but it is difficult to ascertain from his Paper to what extent he succeeded with his experiments.

† "Sur les Courants Alternatifs et la Force Electromotive de l'Arc Electrique." *Comptes Rendus*, Vol. XCI., p. 161, July 19, 1880.

‡ "Observations on the Electromotive Forces of the Brush Dynamo-electric Machine." (Title only.) *Proceedings* A.A.A.S., Vol. XXIX., p. 277 (1880). Prof. Thomas gave the results obtained, and described the method eleven years later in a communication to the Institute of Electrical Engineers, entitled "Notes on Wiping Contact Methods for Current and Potential Measurements," *Trans.* of the American Institute of Electrical Engineers, Vol. IX., p. 263.

them we owe the first set of complete diagrams relating to the performance of this class of alternating-current apparatus. In the same year Meylan ("Sur les Appels Magnetiques," *La Lumière Electrique*, XXVII., p. 220, 1888) used an interesting modification of the method in the investigation of the vibratory magnetic call-bell of Abdank.

In the same year appeared the first definite data with reference to the Westinghouse alternating dynamo at the hands of Messrs. Searing and Hoffmann ("Variation of the Electromotive Force in the Armature of a Westinghouse Dynamo," *Journal of the Franklin Institute*, Vol. CXXIII., p. 93), of Stevens Institute. Then followed in the order named the researches of Ryan and Merritt ("Transformers," *Trans.* Am. Inst. Electrical Engineers, Vol. VII., p. 1, 1889), Humphrey and Powell ("Efficiency of the Transformer," *Ibid*, Vol. VII., p. 311), Tobey and Walbridge (*Ibid*, Vol. VII., p. 367), of Marks (*Ibid*, Vol. VII., p. 324), of Herschel (*Ibid*, Vol. VII., p. 328), of Fortenbaugh and Sawyer (*Ibid*, Vol. VII., p. 334).

In all these investigations the methods under consideration have been used with varying accessories in the problem of the transformer.

In 1890 it was applied under much more difficult conditions to the analysis of the "ball and point effect" by Archibold and Teeple (*see* Nichols, "On Alternating Electric Arc between a Ball and Point," *American Journal of Science*, Vol. XLI., p. 1).

In 1891 Thompson ("Study of an Open-Coil Arc Dynamo," *Trans.* Am. Inst. Electrical Engineers, Vol. VIII., p. 375) determined the intricate changes of induction in open-coil arc-lighting machines by means of the same method, and Ryan ("Relation of the Air-Gap and the Shape of the Poles to the Performance of Dynamo-Electric Machinery," *Ibid*, p. 451) utilised it in his investigations of the influence of the air-gap upon the performance of dynamos and motors. In 1892 Duncan ("Note on Some Experiments with Alternating Currents," *Ibid*, Vol. IX., p. 179) described modifications of the method of instantaneous contacts by means of which the rapidity of reading is greatly enhanced.

Such has been, in brief, the history of a method by means of which in greater degree than of any other we have been able to extend and complete our knowledge of alternating-current phenomena.

To the practical electrician and to the theorist alike, the domain has been one of the most attractive of those which have been developed in recent years. To the electrical engineers of the younger generation the very complexity of alternate-current theory has proved a benefit. It has forced them to increased mathematical proficiency and to more rigorous thinking; it has, indeed, served as an excellent source of discipline. What the problems of submarine telegraphy did for the English electricians who served their apprenticeship during the early days of the cable-laying industry, compelling the development of those sturdy qualities which have been so highly serviceable in every branch of electrical progress since, the intricacy of alternate-current practice is unquestionably doing for the younger school which is growing up to-day in this country. The difficulties which have to be met and overcome in this field of work will have an excellent influence upon the manner in which the problems of the future will be approached.

Another investigation, which owes its existence to a most ingenious application of this same principle of instantaneous contacts periodically repeated, is well known to all of you. I refer to Prof. E. H. Hall's* study of periodic heat-flow in the cylinder walls of the steam engine by means of thermo-elements embedded within the metal and connected momentarily during a selected time-element in the course of each stroke with a sensitive galvanometer. To my mind no more interesting example of the indirect method of studying the phenomena of the time element could be found than this suggestive memoir.

The method of instantaneous contacts has been a fruitful one, and productive of high results; but it does not yield a knowledge of any individual time-element, nor the picture of any single completed cycle. Numerous attempts to record single cycles have been made, the results of which are of considerable interest, because they deal with the more direct study of the time-infinitesimal.

The device which lay nearest to hand, and which by its performance seemed to promise success in this direction, was the magneto-telephone. The investigations of Mercadier (*Journal de Physique*, Vol. IX., pp. 217 and 282) had already paved the way to some extent, when Froelich described his experiments upon the optical representation of the movement of the diaphragm of the telephone, followed almost at once by Thomson.

Froelich† reported his preliminary results to the Electrotechnische Verein of Berlin, in 1887. Elihu Thomson ("An Indicator for Alternating Circuits," *La Lumière Electrique*, Vol. XXVII., p. 339, 1888) brought out his indicator for alternating circuits, an instrument in which the movement of a diaphragm was amplified by levers, and then made visible by optical means (or photographed) in the same year. Froelich's method in its complete form, including the photography of the images from the revolving mirror,* was first described in the year 1889. Some of the curves published in the papers just cited, and particularly the experiments shown in the exhibition of the method at the Frankfort Electrical Exposition of 1891, are most striking; but considering the method by which they are produced, the question inevitably arises as to the part played by the inertia of the moving masses.

Froelich himself points out the necessity of great care in the matter of the adjustments, and of distinguishing the natural oscillation of the plate, which are frequently superimposed upon those to be recorded. Some experience with Froelich's method has convinced me that not only is extraordinary skill necessary in order to obtain, by means of a mirror attached to the diaphragm of a telephone, curves which should represent, even with a fair approximation, the law of whatever periodic changes we may desire to record, but that the attainment of the proper adjustment is a matter so entirely fortuitous, and its maintenance so uncertain, as to deprive the method of much of its usefulness. One may indeed hope to get, by means of successive adjustments, curves which correspond to a known type, but whether in passing to new and unknown types the apparatus retains its faithfulness, is always a question.

The difficulties of the method lay not merely in the tediousness of adjustment, but rather in the tendency to revert to complex forms under changes of condition so slight as to be entirely beyond control. The remedy clearly consists in the elimination of mechanism and the reduction of inertia of the moving parts. Following the suggestion of an assistant, Mr. E. F. Northrup, I tried the following experiments.—

A mercury stream flowing from the contracted nozzle of a funnel (Fig. 1) was made to pass between two metal terminals which were

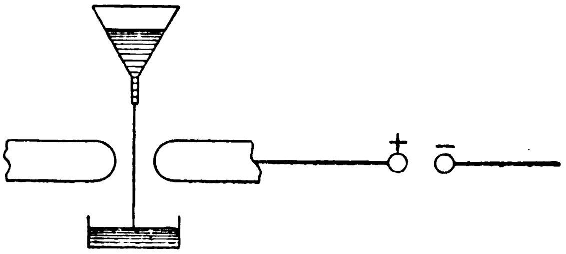

Fig. 1.

attached to the poles of a large Holtz machine. A portion of the falling column of mercury within the electrostatic field was illuminated by means of an arc lamp, and so much of it as could be seen through a horizontal slit was photographed by transmitted light. The sensitive plate was given rapid vertical motion through the field of the camera. When the machine was out of action there resulted a vertical trace running the length of the developed plate. As soon as the machine was put into operation, deflection of the mercury stream occurred. It was the object of the experiment to determine the performance of the stream under the sudden fluctuations of the field which occurred when the Holtz machine was under rapid discharge.

Fig. 2 is from a photograph taken when nearly 100 sparks a second were passing between the poles.

Other photographs were obtained in a similar manner, the deflecting forces, however, being due to the action between the lines of a stationary magnetic field and those of an alternating current traversing the mercury column. The arrangement of the apparatus is shown in Fig. 3. The mercury stream was introduced into the circuit of the alternating-current dynamo, already made use of in the experiments upon Froelich's method. It flowed through a strong magnetic field with horizontal lines. The transverse oscillations of the mercury under these conditions were very apparent. When photographed by means of a camera with optical axis parallel to the lines of force, the stream strongly illuminated from behind and viewed through a narrow horizontal slit, as in the previous experiment, a sinusoidal trace was obtained. All the complexities of the telephonic trace disappeared in these records, and curves corresponding to those of the method of instantaneous contact were always produced. The experiment was made by Mr. Henry Floy, to whose efforts the photographs by Froelich's method are also due. This method has not been further developed. I introduce it here to show that increased accuracy of record may be

looked for as the result of reducing in any practicable manner the mass of the indicating device.

Another attempt to record single periods in dynamo-electric work should be mentioned here. It is described by Moler* in a recent Paper. By means of a D'Arsonval galvanometer with a period of vibration of a few thousandths of a second, curves of varying potential are traced, which show excellent agreement with measurements by the method of instantaneous contacts. The instrument is not free from the errors due to inertia. It is reliable only in recording changes of period considerably greater than its own, but its use is a step in a direction along which progress may be looked for.

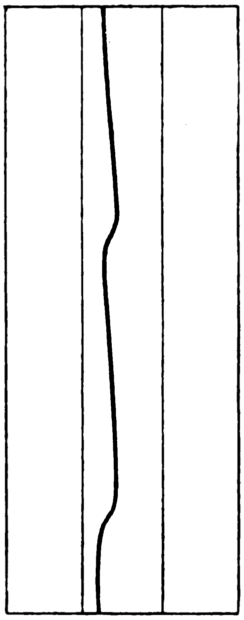

FIG. 2.

Thus far I have dealt with methods of studying periodic changes, the time-elements of which are easily within reach through experimental devices. I might have devoted myself with as good reason to the consideration of recent advances in the study of electrical oscillations of a higher order of frequency. This is a department of physics in which much has been done of late, but so much has been written at second-hand, as well as in the way of original treatment, that further reiteration is uncalled for. The work of Hertz and of his host of followers is familiar to us all. In the study of electrical oscillations even of very high frequency, photography has been used with success, and details of the phenomena of time-elements truly infinitesimal have been secured. By the

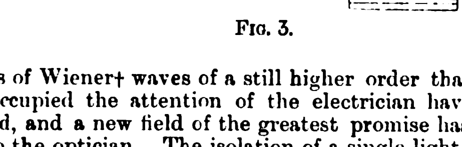

FIG. 3.

labours of Wiener† waves of a still higher order than those which have occupied the attention of the electrician have been photographed, and a new field of the greatest promise has been thrown open to the optician. The isolation of a single-light vibration may indeed still be as far from us as is the inspection of the molecule by means of the microscope, but in the meantime we have in the photography of a system of standing light-waves, an achievement well worth celebrating.

In the investigation of the phenomena of the time-infinitesimal, so far as periodic changes are concerned, we see that the experimenters of the present time are gaining much of detailed knowledge. There is another field equally important, in my opinion, which is as yet for the most part unexplored. The study of the beginnings of changes brought about by abrupt shifting of the conditions of equilibrium is one from which very much may be expected. Already suggestive beginnings have been made, but the researches have not been pushed to the limit of the experimentally possible. Oftentimes interesting observations of what might be termed "startling phenomena" have been recorded, but quantitative results are lacking. Take, for example, the brilliant work of Becquerel (*Comptes Rendus*, 96, pp. 121, 1215, 1853) with the phosphorescope. What a mass of fascinating and suggestive material that *savant* has gathered into the first volume of his book on light! (*La Lumiere*, i. pp. 206-422). What a world of interesting material these preliminary observations present to him who shall undertake to determine quantitatively, wave-length by wave-length, the changes which the radiations from the numerous luminescent materials undergo, beginning with the instant of exposure and following the vanishing light until it is gone.

Of a few isolated cases which have been forced upon us by their practical importance we have some complete knowledge already. With the phenomena in cables when current is suddenly introduced or circuit is broken, we are reasonably familiar. The case of the charge and discharge of condensers has been treated analytically under assumptions the precise truth of which is still to be verified. The detailed study by experiments carried to the utmost refinement, of the very cases which seem to have been most completely covered by theory, is especially important; since in this way only can the assumptions upon which our analysis is based be rigorously determined, and the necessity of modifications be ascertained. For some of this work methods already in use in the study of periodic phenomena will suffice. The curve-writing voltmeter, for example, may be made to give records running to within a thousandth of a second of the instant when a process such as electrolysis, electrolytic polarisation, voltaic action, or the charge and discharge of a condenser begins. Instruments such as the von Helmholtz pendulum, for the isolation of definite small time intervals, may also to be applied to a great variety of progressive phenomena, enabling us to approach by successive steps almost to the very beginning of the changes to be analysed. Concerning known methods let me point out, in conclusion, that photography with the moving plate is a means the limitations of which have not yet been discovered. It is equally applicable to periodic and to progressive phenomena, often with results of unexpected beauty and significance.*

The remarkable experiments of Mach (*Wiener Sitzungsberichte*, 95, p. 764, also 97, p. 41) and of Boys ("On Electric Spark Photographs," &c., *Nature*, Vol. XLVII., p. 415) indicate that the dry plate is still abundantly exposed within intervals so short that the swiftest of modern projectiles give images as of a body at rest.

The laws of electrical resonance have already been so far determined that we can construct condensers, the duration of the discharge of which is a matter of computation, and the precise moment of the discharge of which after a given event is quite within control. This single device, consisting of the exposure of the photographic plate by means of a properly-timed spark, brings under observation a set of time intervals of a new and higher order of brevity. Much is destined to be learned by means of it concerning the nature of matter, and much more, I think, from other, possibly still more powerful, methods which will doubtless be developed when the importance of the study of the time-infinitesimal is more generally recognised.

SPECIAL NOTICE.

With this Number is issued (Gratis) a Tabulated Statement showing the Central Lighting Stations of the United Kingdom in Operation, in Progress, and Projected.

We shall shortly issue with "The Electrician" a COLOURED MAP, showing the Streets in the Metropolis in which Mains for Private Lighting are actually laid, up to January, 1894, together with the areas allotted to the different Supply Companies.

NOW READY.

Volume XXXI. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

Cases for binding Volume XXXI., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

1893.

The painful accuracy which is now expected not only of pure science but of chronology becomes particularly painful when the unfortunate chronicler, denied the privilege of drawing on a fertile imagination, is at the same time deprived of facts that are interesting. Ten years ago it was not so. The great Crystal Palace Electrical Exhibition was a recent event, the first Electric Lighting Act had just been passed, and the ever-memorable Stock Exchange gamble was at its height. The enthusiastic hopes begotten of that marvellous "box of electricity," the Faure battery, and other similar novelties, had found a practical and prosaic expression in the granting of no less than 69 Provisional Orders, of which but seven survive to-day, and engineers were still not quite sure whether to admire or to ridicule the ingenious idea of generating electricity by means of coils strung at the end of prongs three yards long. In fact, electrical engineers were then young and excitable, whilst to-day, though but ten years older, they have become bored and difficult to please. The harnessing of Niagara is no longer the cause of enthusiasm, but, contrariwise, of much destructive criticism; and a neat and workmanlike

device like that by which Mr. W. B. Sayers sought to extinguish sparking, and which, had it been born in '83 instead of in '93, would have been sufficient to float a nicely-graduated series of companies was straightway reduced to the £ s. d. level. Experience in short has "made us sad" and perhaps a trifle captious.

The past twelve months, however, have witnessed a considerable and sound extension of the business of electricity supply, which still continues in this country to constitute nine-tenths of our heavy electrical engineering work. In the metropolis indeed no new central stations have been opened, but a municipal station is in course of erection at Hampstead, and the site for another has been purchased at Islington, whilst one or two other Vestries are engaged in the always deliberate and often dilatory process of considering the question of electric lighting. A better criterion of genuine progress than the coming into operation of new stations, is, however, afforded us by the growth of existing systems. At the end of last year the lamp connections of the twelve companies and one vestry at work in London amounted to some 500,000 8 c.p. lamps; to-day the figure is nearly 700,000 or 40 per cent. more, an increase at once satisfactory and healthy. Prices, moreover, have come down, and dividends, it is said, will go up. In the provinces some fourteen stations have come into operation during the last twelve months, of which no less than ten are municipal; Glasgow, Manchester, Bristol, Dundee, Hull, and Huddersfield being amongst the towns which have started in the electricity supply business. Indeed, were it not for municipal enterprise, the future of electric lighting would not, so far as the provinces are concerned, look remarkably rosy; as it is, towns like Aberdeen, Bolton, Cardiff, Coventry, Dewsbury, Halifax, Leicester, Salford, and Worcester are all committed to large schemes and a total expenditure of not less than £250,000; and the cry is, still they come, Belfast and Edinburgh leading the way. With such solid fare as this we can afford to forget the bubble ventures of 1883.

Electric traction on the other hand, notwithstanding a verdict in the Law Courts favourable to its pretensions, a distinct victory in the Legislature, and the boon of an elaborate set of brand new Board of Trade Regulations, still tarries. The Liverpool Overhead Railway was, it is true, opened to the public on March 6th, and a few weeks later an agreement was signed between Mr. Graff Baker and the Coventry Town Council, which may result in the electrical equipment of the tramways of that city. And as to tramway traction proper, did not a sub-committee of the Corporation of Glasgow report in January that in their opinion the disadvantages of electric traction outweighed its advantages? Evidently we are not to have a traction "boom"; at least, not yet awhile. When the pioneer concerns now at work have proved their right to exist by earning satisfactory and steady dividends, then, and not before, will it be time to deplore the slow progress of electric traction in England. London awaits, as it did this time last year, those lines, running north, south, east and west, which looked so attractive on a neatly-coloured map, and could be made to appear so profitable in a highly-coloured prospectus. The reason is not far to seek. The necessary capital cannot be raised just now. To attribute this to financial depression is but to give the situation another name, not to explain it. The past year has been a year of industrial calamity. The ignorant attack of Labour on Capital has resulted in the precipitate retreat of the latter. A large part of this calamity is the handiwork of labour agitators. They may say that it is no real calamity, but only a drastic remedy. It is a bitter draught which they alone shirk to taste. Millions flow readily enough to Australian loans, but no one dare invest in the proposed London electric railways. Are the so-called friends of the so-called unemployed satisfied? When Capital declines to face the risk of employing Labour, a well-meaning deputation goes whining to the Prime Minister to ask that the taxpayer shall be compelled to do what the capitalist dare not attempt.

Patent litigation, which has hitherto been the bane of the electrical industry, has been this year remarkable for its scarcity. On January 14th Mr. Justice Romer, indeed, delivered his decision in the three-wire case, upholding the validity of Dr. John Hopkinson's well-known and thoroughly straightforward patent 3,576 of 1882; but the action was actually tried at the latter end of 1892, and the decision in question was, therefore, an heritage from an era that it is to be trusted we have passed away from so far as concerns electric lighting. In the United States electrical patent litigation of all sorts still flourishes, and in the early part of the year was responsible for that interesting production known as the Westinghouse "removable-stopper" lamp, a glow lamp with iron leading-iron wires and bottle-neck. With us, 1893 witnessed the expiry of the Edison lamp patent and the Blake and Crossley telephone transmitter patents.

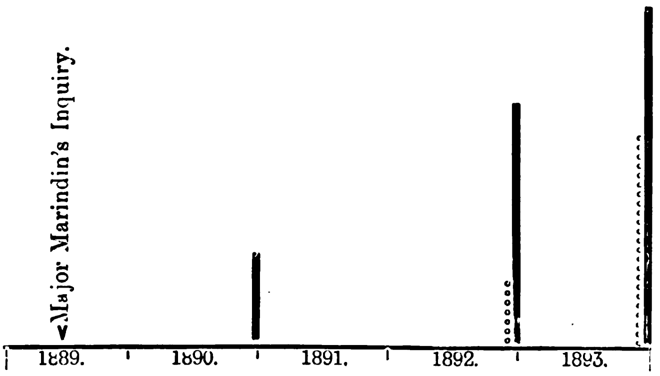
In the telephone world, perhaps the two most noteworthy engineering events were the completion of the Boston-Chicago trunk line, 1,200 miles long, and the telephonic connection of Glasgow with Belfast by means of a cable under the Irish Channel, an achievement that up to the present has not brought much grist to the Post Office mill. The Treasury Minute of May 23, 1892, containing certain proposals of the Postmaster-General to "enable the telephone companies and the Post Office to co-operate in services to the public," still remains without its logical sequence, to wit, a reasonable working agreement between the high-contracting parties. This agreement was originally to have been signed first and then presented to Parliament. Thanks to the persistency of a few members this order of things was reversed; but the draft agreement promised for November is still *in nubibus*. In August, the Glasgow Town Council, ever to the fore in the matter of municipal enterprise, decided to apply to the Postmaster-General for a telephone licence, but to no purpose; telephony, they were told, was beyond the sphere of a municipality. In the telegraph world the carrying-out of the recommendation of the Royal Commission on Electrical Communication with Lighthouses that certain lightships and rock lighthouses should be electrically connected with the main land, in one case by a non-continuous cable, should afford telegraphists a new field for the exercise of their skill and science, and has, in fact, already given rise to some experimenting and much theorising. In submarine telegraphy the year opened with a moderate raising of the rates to Australia, at the request of the Colonial Governments who desired to reduce their contribution to the Guarantee of the companies who had previously reduced the rates by over 50 per cent. to meet the wishes of the Australians. In August a cable was laid between Lisbon and the Azores, and at the end of November the Islands of Seychelles and Mauritius were placed in telegraphic communication with the rest of the world. The gaps which have been made in the ranks of those connected with submarine telegraphy have been both numerous and severe: Sir James Anderson, Sir George Elliot, C. V. de Sauty, H. Weaver, and Oliver Smith have all passed away since the year began. In physical science the only name of note is that of Tyndall, and electrical engineering has lost Anthony Reckenzaun and J. E. H. Gordon.

In what may be termed sensational achievements the year 1893 has been, so far as the purely scientific side of electricity

Digitized by Google

is concerned, a complete blank ; we are evidently in the trough of the wave, a position which has its advantages, and is, after all, as inevitable as the more exalted one. The International Electrical Congress held in Chicago in August was, however, a scientific event of no small importance. Not only did the Congress by giving international sanction to a coherent system of electrical units crown an edifice, the foundations of which were laid by Gauss and Weber some sixty years before, but by drawing the attention of the public to the existence of one set of international units, the Congress may be instrumental in overcoming the apathy in regard to the chaotic state of the more generally used measures. The gathering at Chicago was moreover distinguished from most of the previous meetings of the same kind by its thoroughly representative character, the high order of merit of the Papers read, and the increasingly large share that America, hitherto remarkable chiefly for its practical applications of scientific discoveries, is taking in the pure science work of the world.

DIAGRAM SHOWING THE TOTAL NUMBER OF LAMPS CONNECTED IN THE UNITED KINGDOM.



The height of the vertical columns shows the number of lamps connected, on the scale of 400,000 lamps to the inch, the full lines referring to London, and the dotted lines to the provinces The London total for the end of 1890 is taken from Mr. Frank Bailey's Paper read before the Society of Arts, viz., 180,000; the others, 500,000 for the end of 1892, and 700,000 for the end of 1893, are from our own collected statistics. The provincial totals for the end of 1892 and 1893 are respectively 147,000 and 425,000. "In recounting the history of electric lighting for the past year," says the *Journal of Gas Lighting*, "it is better to begin by acknowledging that this industry has made a certain amount of progress."

REVIEWS.

A Manual of Telephony. By W. H. Preece and A. J. Stubbs. (London: Whittaker and Co. 1893.)

It is a natural result of the Government monopoly of telegraphs in this country that there should be but a small demand for books on telegraphy, and that the joint author of the best one should be the Engineer-in-Chief and Electrician to the Post Office. But the Post Office has up to the present engaged in telephony to so limited an extent that, excellent as its work in this branch has been, it was hardly to be expected that Mr. Preece should also be joint author of the best book on telephony. This, however, is the case, and it is possible that monopoly has checked the production of a good book from other sources. The present work appears to have little in common with the volume on "The Telephone" which was written by Mr. Preece and Dr. Maier in 1888. Many promising instruments have, since that date, dropped out of use, and many important developments, especially in systems of exchange, have been invented and practically employed.

After an introductory chapter, the Bell telephone in its various forms is described, and this is followed by a clear account of the independent invention of the carbon transmitter by Edison, and of the microphone by Hughes; the difference between them, the disappearance of the Edison type, and the general adoption of the Hughes principle are clearly stated. Numerous receivers are described, with excellent illustrations, but no great detail of construction is attempted. Transmitters are then dealt with, and several instruments of a historical, rather than of a practical, interest are wisely kept together in a separate chapter. This section concludes with comparative tests of the performance of a few, too few, patterns. Whether the Johnson transmitter is on account of its results, or because it has not been widely used, passed over with so little notice, we cannot tell, but it is dismissed as having been "devised principally with a view to supply a pencil transmitter free of the Crossley patent." Nothing is said about the shunt which was inserted to prevent the breaking of the circuit when the carbons vibrated too far, a feature of, at all events, historical and scientific interest. A considerable number of varieties of the Hunnings transmitter are described, the tendency of the granules to "pack" is discussed, and methods of preventing it are explained.

Bells, batteries, switches, and magnets, generators, and other apparatus for simple telephone communication, have been treated by other authors, but too often the information has apparently been based upon either manufacturers' catalogues or upon Patent Office specifications. In the present book, not only is the scale of the illustrations in many cases given, but numerous numerical details of resistances as well, together with other practical and useful bits of information. In describing so large a number of instruments only the leading features are touched upon, but the action is always clearly explained. Such apparently small matters as the desirability of hanging receivers ear-piece downwards, to keep them free from dust, and to place them in a convenient position for grasping, are not lost sight of.

Beginning with the simple case of two telephones and an intermediate instrument, the principles of exchange systems are developed in a most lucid style, with the aid of excellent diagrams. The consideration of the effect of the resistance of the line on direct ringing, and on the use of relays, is somewhat beyond the "ironmonger, plumber, and sanitary engineer" who undertakes the "installation" of electric bells and telephones before developing into an all-round electrical contractor. But even this useful and often intelligent individual could with a little attention understand the calculations for battery power and the principles of the simple "bridge" system, so clearly are they written. The necessary current for the bells and relays of the Post Office telephone type and their resistances form the data of the calculations, the working of which is greatly facilitated by a simple scale or diagram, given in an Appendix, whereby the combined resistance of two resistances may be instantly found, by the application of a straight-edge.

Passing on to true exchange systems, the authors plunge into the really intricate subject of switchboards, the English Post-Office system having a short chapter to itself, and including not only an account of the apparatus, but a brief description of the mode of working local and trunk services, testing, construction of "silence cabinets," and telegraph-message working. A chapter on the Law, Mann, Miller, and Bennett-Maclean call-wire systems concludes this part of the work. But here we are only half-way through, for we find half-a-dozen chapters on details of construction and working of switchboards, seven more on miscellaneous switching and other systems, and finally, one on construction of lines, one on wire, one on cables, and one "On the Limiting Distance of Speech."

This last short chapter is occupied, of course, with a statement of the principle, of the application, and of the results of the celebrated K R law. It opens with Lord Kelvin's law of the speed of working submarine cables. The time-constant, $\frac{1}{250}$th of a second, is given for the highest speed in telegraphy, and $\frac{1}{8000}$th of a second for telephony. The K R law is explained to be another form of the Kelvin law, and the well-

Digitized by Google

known constants, as determined by experiment, are given. As this law has been established upon strictly experimental data, and has not been used to found any new scientific theory, its author is fully justified in defending it, on practical grounds, against theoretical attacks. The great difficulty in the theoretical discussion of this law are the data on which K is determined: the capacity must be measured under telephonic conditions, but who is to define what these are? Sidney Smith, on being asked to define the office of an archdeacon, said that he was one who exercises archidiaconal functions.

It has been asserted that if the New York-Chicago line had been built in accordance with the K R law some 1,800 tons of copper, instead of about 430 tons, would have been required, and that the K R of the line is 32,000, more than twice the limit at which, according to Mr. Preece, speech becomes impossible. But on the last page of the book before us we find it stated that there is reason to believe that the K of the New York-Chicago circuit does not exceed 0·04 microfarad per mile. So complete is Mr. Preece's confidence in the K R law that he undertook the sole responsibility of recommending the construction of the London-Paris line, a line on which no preliminary experiments could be tried, and which depended on a severe extrapolation of this law. So strongly has his confidence been confirmed by the result, that we believe he would have no hesitation in using the telephonic quality of a circuit as a mode of measuring its capacity; always, of course, remembering that the capacity under telephonic conditions is understood. We quote the concluding sentence of this excellent manual: "Moreover, there is reason to believe that the beneficial influence of mutual induction in virtually neutralising the effect of capacity will lead to a revolution in long-distance speaking through submarine cables; and it is clear that there is no theoretical reason why speech should not be maintained between Europe and America." If, as seems probable, Mr. Preece uses the word "capacity" in a somewhat special sense, the term mutual induction in this passage may perhaps be employed in an unusual fashion. The reciprocal, as it were, to capacity is self-induction, it is by distributed self-induction that Prof. S. P. Thompson has proposed to cure distributed capacity. The use of mutual induction in that inventor's system is, we understand, rather to link together short lengths of cable each having negligible capacity. The capacity of the whole would then be no greater than that of a part; but, on the other hand, it would be no less. The thoroughness, condensation, and lucidity of this book, which would no doubt have been more easy to write in 750 pages instead of 500, does great credit to the author and the Post Office.

SUMMARY OF ELECTRICAL EVENTS FOR 1893.

January.

The Australian Cable Rates raised at the request of the Colonial Governments (1st).

Judgment given in the Action for Infringement brought by Dr. John Hopkinson against the St. James' and Pall Mall Electric Light Company. Mr. Justice Romer decides that Dr. Hopkinson's Three-Wire Patent, No. 3,576, of 1882, is valid (14th).

Opening of the Hull Municipal Central Station (16th).

Expiry of the Blake Telephone Transmitter Patent, No. 229, of 1879 (20th).

Publication of an Interim Report by the Royal Commission on Coast Communication recommending five Lightships and a certain number of Rock Lighthouses to be electrically connected with the shore (31st).

A Sub-Committee of the Glasgow Corporation report that they are of opinion that the disadvantages of electric traction outweigh its advantages.

Delivery by Prof. W. Cawthorne Unwin of a course of Howard Lectures on "The Development and Transmission of Power from Central Stations."

Belgian Telephone System taken over by the Government.

The American Institute of Electrical Engineers publish a series of important proposals with regard to the forthcoming International Electrical Congress at Chicago.

Dividends declared:—St. James' and Pall Mall Electric Light Company, 7½ per cent.; Anglo-American Telegraph Company, 2¾ per cent.; Newcastle-upon-Tyne Electric Supply Company, 4 per cent.

February.

Expiry of the Crossley Telephone Transmitter Patent, No. 412, 1879 (1st).

Death of Mr. J. E. H. Gordon and M. van Rysselberghe (3rd).

Inauguration of the Liverpool Overhead Railway by the Marquis of Salisbury (4th).

Judgment given in favour of the Leeds Electric Cars by Mr. Justice Kekewich (National Telephone Company *v.* Graff Baker) (4th).

Opening of the Boston-Chicago Telephone Trunk Wire (1,200 miles long (7th).

The price of the Board of Trade Unit reduced by the St. James' and Pall Mall, and Westminster and London Electric Companies, to 6d., with sliding scale discount down to a minimum of 5d.

New form of glow lamp with removable stopper, iron leading-in wires, and bottle-neck, brought out by the Westinghouse Company of America.

Death of Dr. Norvin Green, President of the Western Union Telegraph Company of America.

In an Action brought in America by the General Electric Company against the Beacon Vacuum Pump and Electric Company, the latter brought forward the Göbel Lamp as an anticipation of Edison's; Judge Colt decided that the Göbel Lamp did not warrant stay of preliminary injunction.

The Glasgow Municipal Electric Lighting Central Station comes into operation.

Remarkable results in the reduction of refractory ores obtained by M. Henri Moissan by means of the electric furnace.

Meeting of the National Electric Lighting Association at St. Louis.

Dividends declared:—Kensington and Knightsbridge Electric Lighting Company, 4 per cent.; Telegraph Construction and Maintenance Company, 15 per cent.; Westminster Electric Supply Corporation, 3½ per cent.; Newcastle and District Electric Lighting Company, 5½ per cent.; Electricity Supply Corporation, 5 per cent.; India-Rubber, Gutta-Percha and Telegraph Works Company, 7½ per cent.; Chelsea Electricity Supply Company, 2½ per cent.; Liverpool Electric Supply Company, 5 per cent.; Birmingham Electric Supply Company, 3½ per cent.; Keswick Electric Light Company, 2 per cent.

March.

The Liverpool Overhead Electric Railway opened to the public (6th).

A motion in the House of Commons by Mr. Pickersgill to secure the insertion of a London County Council Purchase Clause in the City and South London Railway Bills defeated by a large majority (9th).

Tramway clauses in the Salford Corporation Improvement Bill withdrawn owing to the demand of the National Telephone Company for a protection clause (16th).

A Select Committee of the House of Commons decide that the preamble of the Clapham Junction and Paddington Railway Bill is not proved. Great opposition was offered by the authorities of the Central Institution and Royal College of Science to the line being taken up Exhibition-road within a few feet of the laboratories (20th.)

Shareholders vote the voluntary winding up of Woodhouse and Rawson United (Limited) (20th).

Papers by Mr. C. K. Falkenstein, entitled "Notes on the Influence of Electricity in Tanning Operations," read before the Institution of Electrical Engineers (23rd).

Rejection of the Kilburn-Victoria Electric Railway Bill by a Select Committee of the House of Commons (24th).

Agreement signed between the Coventry Town Council and Mr. Graff Baker with regard to the working of the tramway system by electricity (31st).

Issue by the Board of Trade of an important memorandum on the effect of using glow lamps in ships' side lights.

Publication of the Report of the Committee of Investigation appointed by the shareholders of Woodhouse and Rawson United (Limited).

Dundee Municipal Electric Lighting Station comes into operation.

The National Telephone Company announced certain reductions in their London tariffs.

Edison "Feeder" patent upheld in the United States.

Dividends declared:—W. T. Henley's Telegraph Works Company, 5 per cent.; Direct Spanish Telegraph Company, 4 per cent.; Anglo-Portuguese Telephone Company, 5 per cent.

April.

Laying of a Post-Office Telephone Cable between Port Kail and Donaghadee (4th).

The Shareholders of Elmore's French Patent Copper Depositing Company (Limited) vote its voluntary winding up (6th).

Digitized by Google

Death of Mr. C. V. de Sauty (11th).
Paper on "Distribution of Power by Alternate-Current Motors," read before the Institution of Electrical Engineers by Mr. Albion T. Snell (13th).
The Islington Vestry decide to undertake electric lighting (18th).
Friday Evening Discourse at the Royal Institution by Prof. A. B. W. Kennedy, on "Possible and Impossible Economies in the Utilisation of Energy" (21st).
The Leicester Town Council decide to accept the Brush Company's tender for a municipal plant on the alternate-current transformer sub-station system (25th).
The Edinburgh Town Council decide to undertake electric lighting (25th).
The Glasgow Town Council appoint a Special Committee "to consider the question of applying to the Postmaster-General for a licence to supply the community with an efficient telephone service."
Dividends declared :—Eastbourne Electric Light Company, 3 per cent. ; Metropolitan Electric Supply Company, 2 per cent. ; Hastings and St. Leonard's-on-Sea Electric Light Company, 5 per cent. ; Eastern Extension Telegraph Company, 7 per cent. ; Indo-European Telegraph Company, 10 per cent. ; Great Northern Telegraph Company, 8/6 per cent. ; London-Platino-Brazilian, 2 per cent. ; New Shanghai Electric Light Company, 7 per cent. ; Western Brazilian Telegraph Company, 2½ per cent. ; Submarine Cables Trust, 6 per cent.

May.

The Faure Accumulator patent upheld by the Court of Appeal in France (5th).
Death of Sir James Anderson (7th).
Paper by Mr. W. B. Sayers, entitled "On the Prevention and Control of Sparking : Continuous-Current Dynamos without Winding on the Field-Magnets, and Constant-Pressure Dynamos without Series Winding," read before the Institution of Electrical Engineers (11th).
Death of Prof. Moses G. Farmer, at Chicago (25th).
Halifax and Ealing decide to borrow £30,000 and £25,000 respectively for electric lighting purposes.
Cardiff authorised to spend £32,500 on electric lighting.
Dividends declared :—Reuter's Telegram Company, 5 per cent.

June.

Important Presidential Address dealing with Gas and Electricity, delivered by Mr. Denny Lane to the Incorporated Gas Institute, at Belfast (13th).
Inquiry by a Joint Committee of both Houses of Parliament as to the telephone protective clauses which should be inserted in private Bills relating to electric traction (19th, 20th, 21st, 22nd, 23rd, 26th, and 27th).
Action brought against the St. James' and Pall Mall Electric Light Company by the Trustees of the Windham Club for nuisance, settled out of Court ; similar action brought against the Electricity Supply Corporation was given in its favour.
Sanction given to electric lighting loan :—Aberdeen, £20,000.
Dividends declared :—Electric and General Investment Company, 25 per cent. ; Consolidated Telephone Construction and Maintenance Company, 2 per cent. ; Eastern Telegraph Company, 6½ per cent.

July.

Publication of the Report of the Joint Committee on Electric Powers (Protective Clauses). Tramways obliged to use insulated or uninsulated returns, telephones to metallicise their circuits (13th).
Action brought by a Strand clockmaker against the Electricity Supply Corporation for damages and an injunction, resulted in the jury deciding that while there was vibration it was very slight (14th).
Death of M. Marié-Davy (16th).
Death of Mr. S. E. Phillips (22nd).
The Commissioners of Sewers decide to sanction the running of telephone wires in the spare tubes of the City of London Electric Lighting Company only upon condition that double wire circuits, good instruments, and £8 rentals are guaranteed (25th).
Opening of the Huddersfield Municipal Central Lighting Station (29th).
The Tunbridge Wells Town Council decide to adopt an electric lighting scheme costing £13,000.
Death of Mr. Oliver Smith.
Dividends paid :—National Telephone Company, 5 per cent. ; Direct United States Cable Company, 3½ per cent. ; Globe Telegraph and Trust Company, 4⅝ per cent. ; Sheffield Electric Light and Power Company, 5 per cent. ; Edison-Swan United Electric Light Company, "A" shares, 10 per cent. ; Oriental Telephone and Electric Company, 2¼ per cent. ; Manchester Edison-Swan Company, 5 per cent.

August.

The Manchester Municipal Electric Lighting Station comes into operation (1st).
The Glasgow Town Council adopt the recommendation of their Telephone Committee and decide to apply to the Postmaster-General for a telephone licence (3rd).
International Electrical Congress held at Chicago. Important Papers were read by Prof. Ayrton on Phenomena connected with the Electric Arc, and by Prof. Silvanus Thompson on Ocean Telephony ; and an International System of Electrical Units and Nomenclature was adopted (21st-25th).
The Southport and Cheltenham Town Councils decide to adopt the high-pressure system of eelctric lighting ; the Stafford Town Council decide to adopt the low-pressure system of electric lighting ; and the Worcester and Coventry Town Councils definitely decide to adopt the alternate-current high-pressure system.
The Zipernowsky-Déri patent for running transformers in parallel, and the Zipernowsky-Déri-Bláthy patent for closed magnetic circuit transformers upheld by the Court of Appeal in France.
The Postmaster-General refuses to grant a telephone license to the Glasgow Corporation.
Cable laid by the Telegraph Construction and Maintenance Company between Lisbon (Portugal) and the Azores.
Dividends declared :—Electrical Power Storage Company, 5 per cent. ; Cuba Submarine Telegraph Company, 8 per cent. ; Brush Electrical Engineering Company, 6 per cent.

September.

Opening of the Municipal Electric Lighting Station at Whitehaven (2nd).
Opening of the Stockholm-Christiania Telephone trunk line (2nd).
Opening of the British Association Meeting at Nottingham (13th).
Postmaster-General promises to present the agreement between the Post Office and the National Telephone Company to the House of Commons in November (19th).
Death of Mr. H. Weaver (20th).
Reduction of the price of glow lamps by the Edison-Swan United Company from 3s. 9d. to 1s. 9d. (21st).
Bill introduced into the United States Senate directing experiments to be made with a view to the establishment of electrical communication with outlying lighthouses and lightships.

October.

Death of Sir Arthur Blackwood, Secretary to the Post Office (4th).
Opening of the Derby Central Station (10th).
Opening of the Queensland-New Caledonia Cable (19th).
Important Paper on "The Artificial Lighting of Workshops," read by Mr. B. A. Dobson before the Institution of Mechanical Engineers (25th).
Inauguration of the Blackpool Municipal Station by Lord Kelvin.
Bolton municipal electric lighting loan of £40,000 sanctioned by the Local Government Board.
The Electricity Department of the Bradford Corporation report a net profit for the financial year, after payment of interest, sinking fund, and arrears, of £1,269.
Dewsbury municipal electric lighting loan of £25,000 sanctioned by the Local Government Board.
Salford municipal electric lighting loan of £32,000 sanctioned by the Local Government Board.
Dividend declared :—Brazilian Submarine Telegraph Company, 6 per cent., plus bonus of 1s. per share.

November.

Opening of the Kingston-on-Thames Municipal Electric Lighting Station (4th).
Paper on "The Electrical Transmission of Power from Niagara Falls" read before the Institution of Electrical Engineers by Prof. George Forbes (9th).
Expiry of the Edison Lamp Patent, No. 4,576, of 1879 (10th).
Issue of Draft Electric Tramway Regulations by the Board of Trade (22nd).
Mauritius cable opened for traffic (23rd).
Statement made by the Postmaster-General in the House of Commons that the loss upon press telegrams amounted to at least £300,000 a year (27th).
Death of Mr. Anthony Reckenzaun.
Strike of Italian telegraph clerks.
The Kensington Vestry reject a proposed municipal electric lighting scheme by a large majority.

December.

Death of Prof. Tyndall (4th).
The Coventry Town Council accept the electric lighting tender of Messers. John Fowler and Company, Leeds, and decide to borrow £20,000 for the purpose of carrying it out (5th).
The City Commissioners of Sewers decide to remove the gas lamps in all streets lighted by electricity (6th)
Statue of Joule in the Manchester Town Hall unveiled by Lord Kelvin (8th).

Digitized by Google

Death of Sir George Elliot (23rd).
Formation of the Northern Society of Electrical Engineers.
Formation of a Governmental Committee to inquire into the subject of the extension of the French Telegraph system, more especially of the French cable system.
Death of Henry Göbel, deemed by some to be the inventor of the incandescent lamp
Foundation stone of the Bolton Corporation Electricity Works laid.
Loan of £15,000 for carrying out a municipal electric lighting scheme at Yarmouth sanctioned by the Local Government Board.
Dividends declared: Swan United Electric Light Company, 7½ per cent.

ELECTRIC LIGHTING NOTICES.

(SESSION 1894.)

The following is a list of the applications for Electric Lighting Provisional Orders deposited with the Board of Trade on or before December 21st last. The total number of applicants is 26, against 18 last year. Of the 26 applicants, 15 are local authorities. Since the publication in our issue of December 1st of the list of applicants who had advertised in the *London Gazette*, six have fallen out of the race, namely, the Kensington Vestry, the Plymouth Gas Company, the Preston Gas Company, Swansea (Crompton and Co.), the Penrith Local Board, and the Torquay Corporation.

THE METROPOLIS.

Districts.	Name of Applicant.
Portions of Beckenham, Croydon, Lambeth, Lewisham, & Camberwell.	Crystal Palace District Electric Supply Company.

THE PROVINCES.

Towns.	Applicants.
Aberdare.........	J. C. Howell (Limited).
Barrow-in-Furness	Corporation.
Bedford	Bedford Electric Light Company.
Birmingham ...	Birmingham Electric Supply Company.
Buxton	Local Board.
Chelmsford	Crompton and Co.
Chepping and Wycombe ...	Corporation.
Chesterfield ...	Corporation.
Clonmel	Corporation.
Grimsby	Corporation.
Guildford	Holloway Electricity Supply Company.
Harrow	Local Board.
Leyton............	Local Board.
Monmouth	Corporation.
Moss Side	Collier-Marr Telephone and Electrical Manufacturing Company.
Oswestry.........	Oswestry Electric Lighting and Power Company.
Peterborough ...	Corporation.
Plymouth	Corporation.
St. Austell	Veale and Co. (Limited).
St. Helens	Corporation.
Shrewsbury......	Shropshire Electric Light and Power Company.
Stirling	Caledonian Electric Supply Company.
Wakefield	Corporation.
West Hartlepool	Corporation.
Yeadon	Local Board.

NEW PUBLIC COMPANIES OF 1893.

The following are the more important limited liability companies connected with the electrical engineering and allied industries registered during the past year, with their capital:—

	Capital.
Acme and Immisch Electric Works	£25,000
George Adams and Sons........................	100,000
Advance Boiler Company	100,000
Aladdin Primary Electric Battery Company	5,000
American River Electric Power Supply Company..	25,000
Anderson, Anderson and Anderson	50,000
Anders Telephone Company	10,000
Ariel Company...	15,000
Sir William Arrol and Co.	150,000
Baily, Grundy and Barrett	10,000
Baily and Grundy, London	10,000
William Banks and Co.	4,000
Belliss (G. E.) and Co.	150,000
Bourne and Grant Electricity Supply Company.....	25,000
John Birch and Co......	40,000
Bolton (R.) and Co..	12,000
Brayton Oil Engine Company	80,000
British Volta Electric Glow Lamp Company	2,000
Caledonian Electric Supply Company	100
Canterbury Electricity Company	50,000
James Carmichael and Co.	65,000
Central American Public Works Company	100,000
Chemical and Electrolytic Syndicate	30,000
Clarke, Chapman and Co.	150,000
Colne Engineering Company	10,000

Digitized by Google

	Capital.
Coventry Electric Tramways	£25,000
Jeremiah Cowdy and Co.	10,000
Credenda Tube Company	100,000
Dalziel's Atlantic Telegram Company	25,000
Roger Dawson	15,000
Detries (J.) and Sons	100,000
Dempster R. and J.	100,000
District Messenger Company of Paris	200,000
Domestic Telephone Company	20,000
Dougill (Alf.) and Co.	12,000
Dover Electricity Company	50,000
Ebenezer Timmins and Sons	20,000
Edinburgh Tramways Company	125,000
Edward Howell and Co.	15,000
Electric and Automatic Engineering Company	10,000
Electric Anti-Corrosion Company	6,000
Electric Construction Company	400,000
Electric Light Regulating Syndicate	1,000
Electric Semaphore Signal Syndicate	3,000
Electrolytic Separation Syndicate	25,000
Electro-Protector Syndicate	10,000
English Electric Carbon Company	10,000
English Electric Manufacturing Company	5,000
Europe and Azores Telegraph Company	200,000
Faraday Electrical Engineering Company	4,600
Farringdon Works	40 000
Ford-Lloyd Manufacturing Company	10,000
Foster Brothers	30,000
Gardiner, Sons and Co.	80,000
Gas Traction Company	100,000
General Electrolytic Parent Company	24,000
Gordon and Fell	100,000
Gorseinon Electric Light Company	1,000
Gravier Dynamo Syndicate	10,000
Harrison, Ainslie and Co.	100,000
Hart, Son, Peard and Co.	35,000
Harvey Steel Company of Great Britain	180,000
Herculite and Electrical Manufacturing Company	12,000
Hirst, Brooke and Hirst	40,000
Thomas Holcroft and Sons	120,000
Incandescent Electric Lamp Company	25,000
Isles (Limited)	20,000
Lamina Accumulator (Elieson's British Patents) Syndicate	12,000
London and Lancashire Electric and General Engineering Co.	20,000
Keay, E. C. and J.	50,000
Lister (R. A.) and Co.	20,000
James MacIntyre and Co.	50,000
Manchester Steel Nut and Tube Company	80,000
Marchent, Young and Co.	4,000
Mazarron Electric Light Company	15,000
Merionethshire Electric Lighting, Power and Appliance Co.	3,000
Merveilleuse Electric Arc Lamp Syndicate	15,000
George Moritz	5,000
William Muir and Co., Manchester	80,000
New Panulcillo	50,000
William Parnall and Co.	30,000
Newington, Priddle and Co.	7,000
North-Eastern Telephone Company	1,000
Omnibus and Tramcar Electric Lighting Company	60,000
Orme's Electric Signal Syndicate	7,500
Oswestry Electric Lighting and Power Company	10,000
Otis Elevator Company	50,000
Perkins and Bellamy	70,000
Pioneer Electric Carriage Company	20,000
Printing, Telegraph and Construction Company of the Agence Havas	130,000
Pyke, Harris and Co.	30,000
Rainbow Engineering Company	20,000
A. Ransome and Co.	59,000
Ramsden, Camm and Co.	50,000
Redruth Electric Supply Company	10,000
Thomas Robinson and Son	120,000
Rollason and Slater	30,000
Rollason's Wind Motor Company	35,000
Rose, Downs and Thompson	50,000
Rotherham Forge and Rolling Mills Company	25,000
Rugby School Electric Lighting Company	5,500
St. Martin's Electrical Manufacturing Company	500
St. Nicholas Construction Company	40,000
Salt Lake and Ogden Gas and Electric Light Company	300,000
Saxby and Farmer	25,000
Shillingford Works Company	10,000
Stannum Metal Company	40,000
Stephens and Co.	20,000
Statter (J. G.) and Co.	20,000
Swan and Harrison Smelting Company	30,000
Swinburne and Co.	25,000
United Gutta-Percha and Rubber Company	50,000
Universal Electric Lighting Company	5,000
Valveless Gas Engine Syndicate	15,000
Wallis and Steevens	60,000
Waterhouse Electrical Manufacturing Company	20,000
Waterhouse Electro-Metric Syndicate	20,000
Zohrab and Bigg's English Patents	32,007

PUBLIC COMPANIES WOUND UP, DISSOLVED, &c., IN 1893.

The following are amongst the limited liability companies which have been wound up during the past year, the asterisk denoting that the company was wound up by order of the Court :—

Abell's Electrical Engineering Company.
Aladdin Primary Battery.
Arcas Plating Company.
*Art Workshops.
Birmingham Telegraph Factory.
Blakey, Emmott and Co.
Boy Messengers and Electric Call Company (business taken over by the District Messenger Service and News Company).
British Electrical Installation Contractors (business taken over by the New British Electrical Installation Contractors).
British Tanning Company.
British Gas Engine and Engineering Company.
Edinburgh Electric Supply Corporation.
Electrical Supplies and Fittings Company.
*Elmore's French Patent Copper Depositing Company.
Electrical Engineering Company of Ireland.
Electric Construction Corporation (business taken over by the Electric Construction Company).
Emile Lansard Syndicate.
Engineering Exchange.
Foreign Electric Date and Time Stamp Company (new Company formed with same name).
Fowler, Lancaster and Co.
Freedman Battery Company.
Gordon (J. E. H.) and Co.
Halifax Mutual Electric Light and Power Company.
Law's Electrical Appliances Company.
*London Metallurgical Company.
London Battery Company.
*Mountain's Wire Manufacturing Company.
Nottingham Electric Light and Power Company.
Panulcillo Copper Company (business taken over by the New Panulcillo).
Powditch (J. R.) and Co.
Steam Loop Company.
Taunton Electric Lighting Company.
Telephone Company of Ireland (business taken over by the National Telephone Company).
Telephone Company of Austria (the Company's Exchanges having been taken over by the Austrian Government).
Thorneburry Miners' Safety Lamp Company.
Wenham Company.
Williamson Electrical Engineering Company.
Windsor and Eton Electric Lighting Company.
*Woodhouse and Rawson United.

The following Companies have been dissolved, or have ceased to exist, in most cases nothing having been done beyond registration, and no business having been commenced :—

Automatic Electrical Corporation.
Canterbury Electricity Supply Company.
Cardiff Electricity Supply Company.
Douglas Patent Block and Electric Meter Company (business taken over by the Electric Meter Company).
Dover Electricity Supply Company.
Electrical Works Construction and Maintenance Company.
Electrical Standardising, Testing, and Training Institution.
Electro-Automatic Fire Extinguishing Company.
Electric Anti-Corrosion Company.
Gloucester Electricity Supply Company.
Gordon and Fell.
Kingston-upon-Hull Electric Lighting Supply Company.
Lane Fox Electrical Company.
Leicester Electric Light and Power Company.
Loughborough Electricity Supply Company.
Manchester Electricity Supply Company.
Penzance Electricity Supply Company.
Portland Electric Light Company.
Provincial Electric Light and Power Supply.
Putney and Hammersmith Electric Light and Power Supply.
Redruth Electric Supply Company.
Sperryn, McDonald and Co.
Stoke-on-Trent Electricity Company.
Theatre Electrical and Specialities Production Company.
Weston-Super-Mare Electricity Supply Company.
Weymouth Electricity Supply Company.

The following changes in nomenclature have been made :—

Charing Cross and Strand Electricity Supply Corporation—formerly the Electricity Supply Corporation.
Hobart Electrical Tramways Company—formerly the Hobart Tramways Company.
Okonite Company—formerly the International Okonite Company.

ELECTRIC SHOT-FIRING IN MINES.*

BY P. HOUGHTON.

It is not my intention to-night to treat the subject of "Electrical Shot-firing in Coal Mines" from a scientific point of view, but more from a practical one, seeing that, like myself, you are all practical men in connection with mining. I take it that we are living in an age of great improvements in connection with all branches of industry, and that, in the branch of mining, the increased depth of our shafts, and the great distance we now go underground, has necessitated the adoption of certain inventions with respect to the general working of our mines, and we find that the men belonging to what we often call the "Old School" have now little or no chance with the more advanced men of our times in the management of our collieries. Hence the importance of us all making ourselves thoroughly acquainted with the new systems under which our mines are now worked. Amongst the number of modern improvements in our mines we find, owing no doubt to the large number of lives that have been lost by explosions and the introduction of the high safety explosives, the question of electric shot-firing has made very rapid strides, and is now being pushed forward by Her Majesty's inspectors of coal mines as the only safe method by which the safety explosives now in use can be fired. In the Inspectors' reports for 1892, Mr. Hedley, Newcastle District, says:—"If necessary to use explosives at all, one of the higher explosives, fired by an electric battery, should be used." Mr. Stokes, Midland District, says:—"In mines worked with safety lamps, the use of a high explosive, fired by electricity, is being largely adopted, and I find, when the proper class of detonator and low-tension fuse, previously tested with a galvanometer, is used, there is little chance of a miss-fire shot, and the work is done with safety." Mr. J. G. Robson, South Wales District, says:—"Electrical firing is, I am glad to say, being extended, and this method with low-tension fuses, previously tested by a galvanometer, appears to give satisfaction. We all know that Mr. Henry Hall strongly advocates the use of the safety explosives fired by electricity in preference to gunpowder. The firing of a charge of explosive through the agency of a slow-burning fuse, though still very extensively practised in mining, presents such decided disadvantages in regard to uncertainty, and, in some cases, of danger when compared with the firing by electricity, that it is not surprising to find what rapid strides the question of electric firing has made. So far back as 1751 the possibility of applying the electric spark to the firing of gunpowder suggested itself to Mr. Franklin, in America; but it was not until some years after the discovery of what is called the electric pile by Volta that attempts were made to apply electricity as the firing agent of gunpowder charges used in mining and military operations. The first practical application of the voltaic battery in this direction was made over 60 years ago by French military engineers, and a few years afterwards Sir Charles Pasley was the first to bring the use of electricity in firing of gunpowder to a practical issue in England. These practical investigations were made with respect to the firing of gunpowder under water, finding that the slow-burning fuse, invented by Bickford in 1831, could only be used at comparatively small depths of water. But to-day the object of electrical firing is one of safety, though the mining fuse patented by Bickford effected an enormous improvement in the firing of charges in mines; yet there is little doubt that accidents in mining would be considerably reduced in number if electrical blasting were more frequently employed, especially in dangerous mines, instead of the uncertain system of firing by slow-burning fuse. Many men have met their doom through going up to a shot in the false belief that the fuse has burned out or become extinguished. In some instances the fuse has been burning for hours; also, explosive mixtures have been ignited and proved fatal to life, owing to the spit of the fuse when touched with the heated wire. With electric lighting the simplest precautions suffice to ensure absolute safety, and in no case where it is necessary that safety explosives have to be used ought they to be fired by any other agency than electricity, because it is not wisdom to adopt a safe explosive and use for its ignition an unsafe means, thereby destroying, to a certain extent, its safety as an explosive. Perhaps, in no other district in this country has the use of the safety explosives and the firing by electricity become more general than in this district of ours, under the inspectorship of Mr. Henry Hall. The electric exploders, cables, and detonators ought not to be treated or used as we might use a pick or spade, to be thrown down, handled, knocked, and kicked about by any or every person in the mine. They are things that require careful handling and using. The object of my Paper is to point out and suggest a better mode of treatment, by first pressing upon you not to rest satisfied by merely knowing that you have an electric exploder to use, but to get a fuller knowledge of both exploders and detonators, so that the carelessness which exists in many cases may be removed, and making the question of electric firing one of perfect safety. We will now consider the different systems of electric firing and exploders now in use, viz.:—

High and Low Tension Electric Exploders.

(*a*) Primary batteries: In this form of battery we have certain elements placed in an exciting fluid, and so arranged that when the circuit is complete, a current of electricity is generated sufficient to fire a certain number of shots; but these, when not in use, are constantly wasting, owing to local action. (*b*) Secondary or storage batteries are more lasting and more under control than primary batteries, as local action is modified, and they only give off when required a portion of the current previously supplied to them by a primary current. The disadvantages of the above forms are numerous, owing to the bulkiness and weight of the cells, and also from the presence of liquids, which makes it inconvenient for them to be carried about without spilling the acid contents. Currents can be more conveniently produced by mechanical contrivances in the various forms of exploders. They are very powerful, and, as the name denotes, are made on the dynamo principle. They are very permanent, and require little attention compared with primary and secondary batteries. Of course, in time they become weaker, and require re-magnetising, but, with proper treatment, will last a long time. Care should be taken where they are stored in the mine, and in removing them from a warm to a cold place or from a dry to a damp part of the mine, as these changes may to a certain extent affect them. Exploders are also called accumulators and generators. With accumulators you turn the handle with a quick action, 15 or 20 revolutions, and after you have ceased turning, press the knob or button.

In the generators you connect firmly one end of your firing cable to the shot, the other end to the terminals of the exploder, then turn the handle with a firm quick action three or four revolutions, and then while still keeping up the speed, the button should be firmly pressed to fire the charge. These are more adapted for coal shots, but for stone headings and sinking shafts where a number of shots require to be fired simultaneously a much larger and stronger exploder would be required. At all collieries where electric firing is in operation machines ought to be got to test the exploders from time to time as this would be a means of preventing the inconvenience and loss arising from miss-fire shots owing to weak exploders. For high-tension exploders you require a voltmeter to test the pressure of your current. If your firing cable detonator and connections are right for firing, an exploder registering from 30 to 40 volts ought to explode the charge, but as it may happen at times that the explosive substance in the fuse head is not sufficiently sensitive you will require a much higher voltage. Hence the importance of having an exploder of sufficient reserved power. This exploder registers 120 volts, and is supplied by the Roburite Explosive Company, being about the strongest for ordinary coal mining I have seen, and one wherein you have a great reserve of power. For low-tension firing you require a galvanometer, which I will explain when dealing with the testing of electric fuses, but before leaving the question of exploders allow me to give one word of caution—that whoever the person in charge of the firing he ought to keep the exploder in his possession, and should be the last person away from the force after connecting the firing cable to the fuse, as accidents have happened caused by connecting to the exploder, and persons being left in the vicinity of the shot; also in case of miss-fire always disconnect your firing cable from the exploder before any person returns back to the shot. We now come to the detonators used for firing the charge, and as we cannot explode any of the safety explosives only by means of a detonator, and that accidents have occurred through the tampering with these things, it is very important we should have a knowledge of what they consist, so that we may handle them with a little caution, thereby overcoming the danger. As commercially used, they consist of a metallic case, usually of copper. There are several sizes made, which vary in dimensions and in the amount of explosive contained in them. As a rule the very weak detonator, or those containing a very small quantity of explosive, is used for detonating dynamite, &c. Stronger ones, numbered 6, 6½, and 7, are used for such explosives as roburite. Too weak a detonator should never be used with any class of explosive, for in no case with a too weak detonator do you get a complete combustion of the charge, and may at times have a miss-fire altogether. I have known cases where the explosive has been blamed, but, when investigated, it has been the fault of having too weak a detonator. The explosive used is pure fulminate of mercury, or a mixture of the same with chlorate of potash and occasionally other substances. Fulminate of mercury is by far the most practical in use. When pure it is white. It is extremely explosive, and has very violent local action. It explodes with slight friction or percussion, or when heated to 360°F. Persons ought to avoid tampering with an open detonator, and should not insert anything to produce any friction. The detonators I have just described go to make both.

* Abstract of a Paper read before the Lancashire Association of Colliery Under-Managers, November, 1893.

High and Low-Tension Fuses.

The low-tension fuse is made up as follows:—Two small copper wires of a certain length are attached to a suitable flat piece of insulating material, such as wood or gutta-percha. The ends of the wire are put through the insulated piece very firmly a certain distance from each other, generally about a quarter of an inch. The ends of the two wires protrude a little, and from each is soldered a bridge of very fine platinum wire. The small piece of insulated material with the bridge of platinum wire is then enclosed in a small cap or case made of very stiff paper or thin cardboard filled with a very small quantity of fine explosive substance, and sealed up at the end; this head, when complete, is then enclosed, and made secure in the copper case, called a detonator, containing the fulminate of mercury. The current meets with a much greater resistance when coming in contact with the fine platinum wire, which becomes heated sufficiently to ignite the explosive substance. That in turn explodes the fulminate of mercury. The advantage of the low-tension fuse is, it can be tested before being used by attaching the fuse wires to a galvanometer, and passing through the fuse from the meter a very feeble current of electricity, which is not sufficient to fuse the platinum bridge. If the fuse is perfect a movement is shown by the needle of the galvanometer. In testing detonators, or what is called low-tension fuses, care should be exercised by putting the detonator in a small tube or pipe, as it might happen for the detonator so tested to explode. The High-Tension Fuse: These differ a little from the low-tension fuse. Two small copper wires of suitable length are covered with gutta-percha, or other insulating material, for about half an inch at the end, care being taken that the wires do not come in contact with each other, and that the ends of the wire are bare (there is no bridge of fine platinum wire). The two wires insulated are inserted in the small head or case containing the explosive substance, which, on the current passing from a high-tension exploder, a spark leaps from wire to wire which fires the explosive substance, and that the fulminate of mercury. The high-tension fuse cannot be tested on a galvanometer, so care in the manufacture of these ought to be exercised that the ends of copper wire in fuse head is a proper distance from each other, and the priming explosive is not of an inferior quality, not put up damp, as miss-fires may happen owing to the composition in the fuse head not being sufficiently sensitive, especially if you have a weak exploder. In addition to exploders and electric fuses we want a good firing cable. This is usually supplied in twin form, the two wires being insulated with rubber or gutta-percha, and these wrapped with cotton or tape. Cables can be had any length required, and suitable for different classes of work. They are used for connecting the fuse wires at the shot-hole and to the exploder. For low-tension firing the diameter of the wires of cable require to be larger than for high-tension, the diameter of wires being regulated according to the distance from shots to battery and number of shots to be fired, as the resistance met with in a small diameter is so great with low tension that the power is lost in the cable. We now come to the different methods and ways of connecting a number of shots together for electric firing, the two principles being—

I.—*In Series, or Single Circuit.* II.—*Parallel, or Compound Circuit.*

Series, or Single Circuit.—This method is principally adopted with low-tension firing, as you are unable to get the same number off in parallel with low tension, the reason being that in parallel you increase the thickness of the fine platinum wire by the combined number of shots; hence the current passes on without meeting the resistance in the platinum wire sufficient to fuse it and explode the detonators, the current being too much divided.

Parallel, or Compound Circuit, is more adapted for high-tension firing. From experiments we gather that with low-tension firing we connect in series, or single circuit, that is, in a continuous circuit from one end of the firing cable to the other, care being taken to have the firing cable, the wires of which must be of sufficient thickness to get the full strength of the current to the shots, and that for high-tension fire we connect in parallel. It is possible to fire a number of shots simultaneously in series or single circuit with the high-tension exploder, but I have seen where the current has passed on and left one or two of the shots not exploded. Low-tension firing, with the shots connected in series for firing a number simultaneously, is the most generally adopted. There are two other ways of connecting, namely, combination and long-distance grouping, but, as these are more adopted for surface operations than coal mines, I will not take up any time in describing them, but will briefly consider the advantages of electric firing in mining. I have already pointed out the advantage and importance of electric firing in point of safety with reference to the safety explosives now in use in our coal mines. The advantages to be derived from electric firing in sinking shafts where black powder is often used to me is very great, and I have often wondered why electric blasting has not been more adopted in this class of work, especially when we consider the danger and risk in what is called "matching" the shots at the bottom of a sinking shaft. Accidents would become a thing of the past if electricity was the means of exploding the charges. In miss-fires caused by slow-burning fuse there is a great loss of time and danger; but with electric firing no time need be lost, because after disconnecting your cable from the battery there is no danger of the charge exploding. There is a great advantage in the firing of a number of shots simultaneously by electricity, both in stone headings and sinking shafts, in their power and saving of labour, because by this method of blasting it takes a less number of shots for the same work; also, the holes can be put in deeper, thereby getting hold of more ground. Much has been said of late with reference to miss-fire shots by electric firing, and the danger attending the recovery of the detonator, accidents having happened to the collier or some other person cutting too near the old shot-hole, and coming in contact with the detonator. The introduction of the safety explosives in coal mines having necessitated the use of a detonator for their ignition created a new danger, seeing they were put in the hands of persons to use who, up to a very short time back, had neither seen nor heard anything about a detonator; and even to-day there are hundreds in our coal mines who have neither seen one nor do they know anything of electric blasting. And only during this last month I visited a colliery where neither the under-manager nor the fireman had seen an electric exploder, or knew anything with reference to electric firing. With me prevention is better than cure, and, as I have already stated at the commencement of my Paper, we ought to make ourselves thoroughly acquainted with all those things that have been introduced for the safe working of our mines, not knowing how soon we may be working under conditions that will force these things upon us. I contend, owing to electric firing having been placed in the hands of persons not previously having had any knowledge of either the explosive detonators or the electric appliances for firing purposes, accidents have happened, not altogether through carelessness, but more from ignorance of those things which have fallen in their hands to use. But as knowledge is gained of what a detonator consists of, and its danger when tampered with, so will men become more cautious when a miss-fire happens to regain the detonator. We may consider more fully the causes of miss-fires from electric firing; and I give here, by the kind permission of the Roburite Explosive Company, some very useful instructions. Miss-fires by electricity may be caused by the following:—(*a*) Weak Exploders.—These with constant use become demagnetised, the connections become weak and corroded, the gearing damaged or worn. (*b*) Defective Firing Cable.—With constant coiling and uncoiling, and use at the face, the insulation becomes unreliable and defective, and then a cross connection is made, which prevents the electric current reaching the face. (*c*) Faults in Manipulation.—Cutting the fuse wire in tamping, kinking, or twisting them, rubbing off the insulation, bad joints, careless handling of the exploder when in the act of firing. (*d*) Faults with Fuses.—Allowed to get damp, not adapted to the exploder used, or suitable under the conditions existing, carelessness in manufacture of them. In charging a shot-hole great care should be exercised. (*a*) That the electric detonator is inserted and secured in the explosive. (*b*) That the fuse wires are kept from the explosive charge along the side of the shot-hole. (*c*) That the tamping used be not of a gritty or cutting nature. (*d*) That the leading wires be not kinked or otherwise damaged while ramming. (*e*) That the joints between the ends of the fuse wires and the ends of the firing cable are perfectly made by the two copper wires being quite clean, bare, and well twisted together. (*f*) That the ends of the firing cable connected to the terminals of the exploder are clean, bare, and firmly screwed down. In firing a shot great care should be exercised. (*a*) That the firing cable wires are not connected to the terminals of the battery while any workman is at the face while the shot-hole is being charged or while the fuse wires are being connected. (*b*) That the operator's hands do not touch the terminals of the exploder. (*c*) That the handle of the exploder be turned with a firm, quick action three or four revolutions, and then while still keeping up the speed the knob be firmly pressed to fire the charge. The strength of the current depends mainly upon the rapidity with which the handle is turned.

SLOPER'S INTERCHANGEABLE TELEPHONE SYSTEM.

Messrs. Gent and Co., of Leicester, are introducing a system of telephones, the invention of Mr. Thomas B. Sloper, of Devizes. It is on the interchangeable system and is specially adapted for factories, warehouses, institutions and dwelling-houses. There is no central station, the services of an attendant, therefore, not being required. The new system is so arranged that it is impossible to leave an instrument in a condition in which it interferes with the talking of other stations, or in a condition in which it cannot itself be rung up.

Digitized by Google

These instruments are made in three classes. Class A, Fig. 1, is designed for connecting telephones with electric bells in private houses. Class B, Fig. 2, is made up with microphone, receiver, and bell complete. Class C instruments, Fig. 3, have connections for independent circuits, and they form a most complete system of telephones for either private houses, institutions, or business premises.

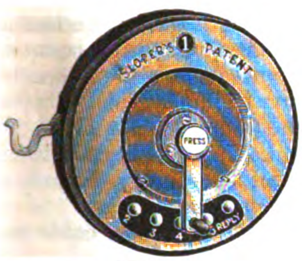

Fig. 1.

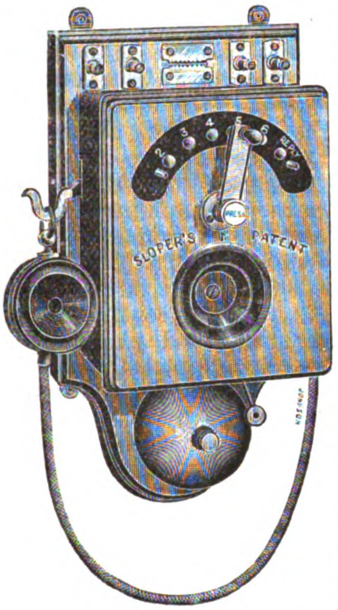

Fig. 2.

By means of a small lever shown under the switch hook in class "C" the earth or return circuit is cut off, and the current goes by the line of one station and returns by that of the other, thus giving a complete metallic circuit between the two stations, out of contact with the earth or return wire. This renders it quite impossible for the other stations to disturb the circuit while in use, or to over-hear.

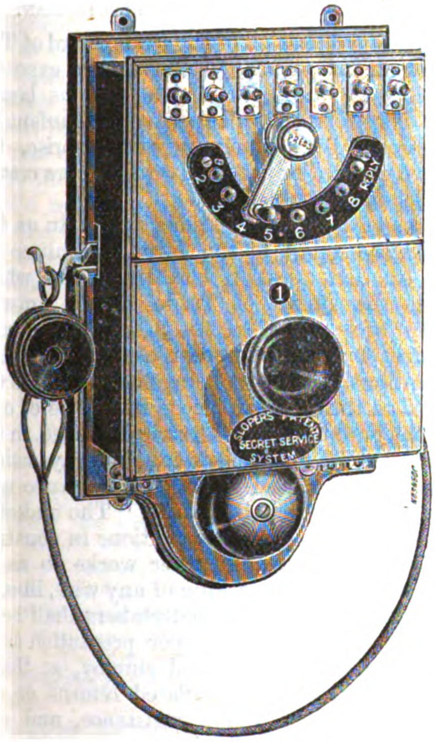

Fig. 3.

By means of a simple addition a reply signal can be received and given, which is a very great advantage for business purposes. Thus, suppose a manager at a factory rings up a certain department, say at No. 15, in all other systems it would be necessary to listen at the receiver until someone replied, and in case there was no one at No. 15 to answer, it would be time wasted, in addition to the annoyance. By the Sloper system it is only necessary for the manager to ring up No. 15, when he would wait until he received a reply signal, and if no reply came he would know there was no one at No. 15 to answer. The reply signal does not ring the ordinary bell, but causes a buzzer to sound; thus a direct call can always be distinguished from a reply signal. On receipt of a call, the "called" station (in the above case No. 15) puts his switch over to "reply," and presses a stud which causes the buzzer to sound at the station from which the call came. The ringing contact is combined with the switch in a very simple manner, so that it is only necessary to move the switch to the line required and press the switch itself.

A circular just issued by Messrs. Gent and Co. gives a few interesting diagrams showing how they can be connected to suit various purposes.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

C. B. Harness, Managing Director of the Medical Battery Company, J. M. M'Cully, and C. B. Hollier, again surrendered on Wednesday before Mr. Hannay, at Marlborough-street, to their bail, to answer the charge of having conspired together to obtain money by false pretences from various persons.

Mrs. MARIANNE CAROLINE EBBEN said that in January, 1892, she went with her husband to No. 52, Oxford-street. The gentleman she saw said that in three months he would make her walk as well as she used to. She was to pay 100 guineas down. The treatment did not do her any good.

Cross-examined by Mr. AVORY: Her husband was present when she wrote the cheque for 100 guineas. She had been under the treatment of two or three doctors for about eighteen months, but they did her no good. She was so disappointed that she was not better from the treatment she received that she communicated with her lawyers with the view of getting her money back. She knew that her lawyers commenced an action against the Company to recover her money, and the result was that it was settled by her receiving £75 and the expenses to which her lawyers had been put. That occurred about twelve months ago. The case was settled out of Court.

Mr. EBBEN, the husband of the last witness, cross-examined by Mr. AVORY, said the action that was brought to recover the 100 guineas was settled to the satisfaction of the witness. It was arranged in the settlement that all imputations on both sides should be withdrawn.

W. R. SELLMAN, recalled and cross-examined by Mr. AVORY, said that from 1887 down to the time he (witness) left there was always a qualified medical man on the premises in Oxford-street. As far as he knew there was no description of Mr. Harness on the premises as "Dr. Harness" after January 6, 1890. He was present at lectures given at the premises six years ago on electricity and chemistry. He remembered M. Loreau coming to the premises and heard that he was connected with the Salpêtrière Hospital, Paris. M. Loreau stayed at Oxford-street about two years, and during that time was engaged in designing improvements in the electric belts. He (the witness), as a matter of fact, treated numbers of persons, who went away either cured or very much better. Most of them wore belts as part of the treatment. Some of the persons that the witness treated sent him personal testimonials in addition to the ones they sent to the Company. About three weeks after he was arrested the prosecution first approached him to give evidence. Before he was arrested the prosecution had never asked him to do so.

Mr. W. H. JONES said that he visited 52, Oxford-street in 1892 to be treated for rheumatism in the feet. He was taken to a room, where a wire brush was passed about his ankles. He was then told that his case was serious and likely to get worse, and was advised to try one of the electrical belts, the price of which was five guineas. He said that he did not think he could afford so much, and was informed that it would be useless for him to have a cheaper one, as he required one of the strongest belts. At the time he had not five guineas about him, and he was asked if he had a banking account. He replied that he had, and then a blank cheque was procured, and the witness filled it up for five guineas. He wore a belt for about a month, but it did him no good. Acting on instructions he returned to the Medical Battery Company after the lapse of a month, and was told to wear the belt for a couple of weeks longer. Finally, he was given a new belt, and some weeks after the Company wrote, asking for a testimonial, when he replied that their belts were worthless.

Cross-examined by Mr. AVORY: He had consulted medical men about his complaint, but they had not cured him. He did not demand his money back from the Company. He did not think that what he said was a letter asking for a testimonial was merely a circular inquiring about the state of his health.

Mr. AVORY said that the defendants were anxious that the magistrate should visit the establishment in Oxford-street and examine the appliances there, but Mr. Hannay did not think there was any necessity for that.

The case was again adjourned for a week, the same bail being allowed.

Anglo-American Telegraph Company v. Compagnie Française du Télégraphe de Paris à New York.

The appeal in this action came before the French Courts last week, and was again adjourned for a month.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 15, 1893.

The "Novak" Lamp Suit.—The decision of the Court in the Novak lamp case, argued at Hartford, Conn., last week, is awaited with much interest, as the issue is entirely different from that of the other great lamp cases. The validity of the Edison patent is not attacked, the contention being that of non-infringement. The Edison lamp patent rests upon a combination of a carbon filament and an all-glass exhausted receiver with leading-in wires; the defendants claim that as they employ an inert gas under a pressure of only one six-hundredth of an atmosphere they do not infringe the combination. It was claimed in the argument, and admitted by the plaintiffs, that vacuum lamps are not efficient unless the exhaustion is carried to at least one three-hundred-thousandth of an atmosphere. The plaintiffs also admitted that a lamp containing gas under the pressure of that in the Novak lamp would not blacken as readily as a vacuum lamp. Should the suit be won by the defendants it is probable that they will be met by a claim that all the points in their patent are covered by other patents of Edison relating to the use of inert gases in lamps.

The San Francisco Exhibition.—The midwinter Exhibition at San Francisco promises to be unusually successful from an electrical point of view. Mr. W. F. C. Hasson, who has charge of this department, will introduce several novel features, including a tower of light, and the electrical equipment thus far comprises generators aggregating more than 2,000 horse-power.

Cheap Lamps.—The General Electric Company has just announced a reduction in the price of incandescent lamps from 44 cents to 32½ cents.

CORRESPONDENCE.

THE MORDEY ALTERNATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—Allow me to thank you for your editorial remarks on Prof. Forbes' criticism of the synchronising effort exerted by my alternators.

Put briefly, the experiments alluded to consisted in placing between two alternators a resistance considerably more than was required to absorb the whole output of one of them. As even under these circumstances the machines did not actually break out of step, I regarded the experiments as very satisfactory, and it was with the greatest astonishment that I heard Prof. Forbes cite them as showing the contrary.—Yours, &c.,

W. M. MORDEY.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your leading article (December 22nd) on the Institution of Electrical Engineers is an example of the destructive order of criticism, and I beg leave to express my regret that it should have appeared in such a paper on such a subject.

I might be disposed to revive your confidence by a more hopeful view of the prospects, but I am writing as a Member, and it is more becoming that, whatever the present shortcomings may be, they should be dealt with among ourselves and not paraded before the public.

Pemit me, however, to say, with reference to your fiat, that one must look elsewhere if one wants anything done—that the Institution is adequately representative of electrical engineers, and its future, with all its possibilities, rests with them.—Yours, &c.,

W. L. MADGEN.

8 and 10, Charing Cross-road,
London, W.C., December 27, 1893.

LA SOCIÉTÉ GÉNÉRALE DES TÉLÉPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly allow me to correct, through the medium of your excellent paper, various rumours set on foot with regard to the present position of "La Société Générale des Téléphones." As you are aware, this Company has been, and is still, carrying on an action against the French Government for the recovery of the amount due for its telephonic communications and plant taken over by the State. This lawsuit, which is likely to be protracted for a considerable time, placed the Company in a position of great difficulty, as contractors to the same Government, and hampered their energies as manufacturers. To avert these difficulties it has been decided to entirely separate the lawsuit from the manufacturing business, in order to gain a free hand. Consequently the "Société Générale des Téléphones" is to carry on the lawsuit. On the other hand, the various works of the Company, namely:—

1. For the construction of telephonic and telegraphic instruments and plant and appliances for every branch of electricity, situated 2, Rue des Entrepreneurs, Paris;
2. For the manufacture of india-rubber goods, cable and wire, &c., at Bezons (Seine-et-Oise);
3. For submarine cables, at Calais, were amalgamated, on December 9th last, with the well-known firm of "Menier," Paris, manufacturers of india-rubber goods and cables, and are to be carried on under the title of "La Société Industrielle des Téléphones."

Thus the two most powerful firms of the kind in France, which used to compete with each other, are now united, and the new Company, having got rid of an interminable lawsuit, has doubled its producing powers, and intends carrying on business with renewed vigour.—Yours, &c.,

G. A. NUSSBAUM,
General Agent for La Société Industrielle des Téléphones.

ELECTRIC TRACTION AND THE BOARD OF TRADE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Since the publication of the draft Board of Trade Regulations for electric tramways, we have been expecting to find attention called in the Press to the serious bearings these Regulations, if confirmed, will have on the infant industry of electric traction. But, much to our surprise, the matter seems to have escaped notice, and we therefore crave space for a few remarks on the subject.

In the first place, the Regulations appear to us to be out of harmony with the report of the Joint Committee which considered the traction question last June, and which recommended that the Board of Trade should draw up rules calculated to give effect to the Committee's views. The following extracts from the report clearly indicate the Committee's intentions, the italics being ours:—"The Committee, having regard to the evidence before them, are of opinion that it is not, in the present state of electrical science, in the interest of the public to insist upon electrical tramways using an insulated return conductor, and that such insistance would retard the development of electric traction." "The undertakers shall take all reasonable and proper precautions in constructing and using their lines, circuits, and other works so as not injuriously to interfere with the working of any wire, line, or apparatus. . . . provided always the undertakers shall be deemed to take all such reasonable and proper precaution as aforesaid, if and so long as they adopt and employ, at the option of the undertakers, either such insulated returns or such uninsulated metallic returns of low resistance, and such other means of preventing injurious interference with the electric wires, lines, and apparatus of other parties, and the currents therein, as the Board of Trade shall direct, and in giving such directions the Board *shall have regard to the expense involved and to the effect thereof upon the commercial prospects of the undertaking.*" The Board of Trade are empowered by Section 3 of the Report to make rules "for regulating the employment of insulated returns or of uninsulated metallic returns of low resistance, for preventing fusion or injurious electrolytic action on gas or water pipes, or other metallic pipes, structures, or

Digitized by Google

substances, and for minimising, *as far as is reasonably practicable*, injurious interference with the electric wires, lines, and apparatus of other parties, whether such lines do or do not use the earth as a return." In their third and fourth recommendations the Committee express themselves altogether in favour of metallic circuits for telephones and railway block signals. Briefly, the Committee considered that, although every precaution was to be adopted in favour of earthed telephones and water pipes, the existence of these things was not to stop, nor to even hamper, electric traction. The Board of Trade respond to this expressed intention by proposing their Regulation No. 14:—"In the disposition, connections, and working of feeders the Company (undertakers) shall avoid injurious interferences with any existing wires." This was exactly the view of the National Telephone Company when they tried to stop the Leeds tramway. It was a view they could not persuade Mr. Justice Kekewich to adopt, it was a view they could not persuade the Joint Committee to adopt, and yet, after everything that has passed, the Board of Trade calmly go back to it and seek to make it law. There is no qualification such as the Committee indicated to the proposed regulation, and its adoption will place electric traction in a worse position than ever. By regulation No. 15 "sparking at the rubbing and rolling contacts in any part" is absolutely forbidden. Is that "reasonably practicable?" We say that it is not. The indifference displayed by the electrical profession in the matter may be, perhaps, due to the knowledge that the Board of Trade intend to take the opinion of the Council of the Institution of Electrical Engineers on the regulations before issuing them, but a word of warning appears necessary on this point. The National Telephone Company are most influentially represented on the Council by gentlemen who are, or have been, their retained experts. No doubt it may be said that these gentlemen will not allow their conduct at the Council to be influenced by their retainers, but can they avoid insensible bias, and would it be just to their employers if they did? We would suggest that the only proper course is for the Council to exclude all such partisans, whether for or against traction or telephones, from their deliberations when the rules are under consideration. That the National Telephone Company are alive to the occasion would appear to stand confessed by the circular letter issued from their offices on December 8th to their *employés* and others suggesting that they should substitute on their ballot papers the name of one of the Company's officials for that of one of the Council's candidates, and also endeavour to influence their friends to do the same. The manœuvre did not succeed, but it is significant. It is also noteworthy that the list of Mr. Ansell's proposed representative Council does not include any members for traction, whilst telegraphs and telephones are to be provided with three.—We are, yours, &c., BENNETT AND DRUCE.

Fishergate, Preston, December 30, 1893.

THE PAST YEAR'S WORK.

MESSRS. ROWLAND BARNETT AND CO.—This Newcastle firm have been busy during the past year, and included in the work completed is the supply of a complete electric lighting plant for the Times Steamship Company's "Juno," the plant for the Bitchburn Colliery, and the lighting of about 50 business premises, &c. The vast increase of work has necessitated the taking of larger premises for town show-rooms and offices, and the extension of their works at Walkergate. The firm obtained a gold medal at the recent Trades and Industrial Exhibition at Newcastle for their new North-Eastern dynamo.

MESSRS. BENNETT AND DRUCE.—Amongst the installations carried out during the past year by this Preston firm are included the premises of Messrs. Walker and Sons at Hyde, near Manchester (nearly complete), and the mills owned by Mr. Levi Fish, by Mr. John Humber, and by Messrs. Hartley Bros., all of Preston.

MESSRS. JOHNSON AND PHILLIPS.—Business in this firm's electric lighting department during 1893 was well maintained. Several of the branches have been exceptionally busy, necessitating an unusual amount of overtime in order to complete orders for cables, arc lamps, accumulators, &c. This satisfactory state of things has induced the firm to make fresh additions to the buildings and machinery at their Charlton Works, which are now in progress. During the year the contract for laying the Brooks system of mains for the Chatham and Rochester public lighting has been completed, comprising about twelve miles of conductors fitted with junction and terminal boxes, house service, &c. The Brooks system is well known to our readers, and possesses many advantages. Large orders for the well-known Brockie-Pell arc lamp have necessitated the fitting-up of new shops to meet the ever-increasing demand. These lamps have been adopted for the public lighting of Hull, Blackpool, Bristol, Portsmouth, Londonderry, Oxford, Burnley, &c.; and are also in use at the Imperial Institute, Woolwich Arsenal, the Winter Gardens at Blackpool, the Bute Docks, Cardiff, and at the principal stations of the London and North-Western and Great Northern Railways. The Continental and Colonial demand for these lamps has also made satisfactory progress. During the year the D.P. storage batteries manufactured by this firm have been in satisfactory demand. During 1893 Messrs. Johnson and Phillips have taken up the manufacture of the Perry meter. Large numbers of these have been made, and plant has been put down sufficient to cope with a considerable demand, which orders already to hand justify the firm in anticipating. Large multipolar machines, whose self-regulating qualities show a high degree of excellence, have been a special feature of the year's work, and included in the orders received have been a novel motor-alternator, for use at the University College, London, arranged to work either off the public mains or by means of independent belt power, and so designed as to demonstrate the phases of alternate-current working; and also a large multipolar steam dynamo for the military electrical School at Chatham. Messrs. Johnson and Phillips's latest form of transformer is commanding a large sale, those recently made for the Bristol Corporation being arranged for the three-wire system.

MESSRS. F. F. REID, FERENS AND CO.—Included in the electric lighting contracts completed by this Newcastle firm are the following:—A 260 16-c.p. installation at the Haswell Co-operative Stores, worked by a Hornsby-Akroyd engine, and including a battery of 53 cells. Four electric motors have been supplied for this installation; one for raising flour in sacks to the flour lofts, one for cutting hay and crushing oats, one for washing and drying currants, and the other for driving a ventilating fan. At Eppleton Colliery (Hetton) plant has been put down for 630 16-c.p. lamps, in addition to eight 2,000-c.p. arcs for lighting the railway siding, &c., for the Cornsay Colliery Institute. Mr. J. H. Love has presented an installation of 50 25-c.p. lamps for the use of the miners, the work being carried out by the above firm. Another contract has been carried out at the Widdrington Colliery, including the lighting of the owner's house, which is situated 1,300 yards distant from the dynamo house. For the Harton Coal Company's Colliery, Whitburn, an installation has been put down for electric lighting the schools owned by the Company.

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—This Company report that they have been extremely busy in all departments during the past year. Their vulcanised cables have had a large sale, and they have supplied considerable quantities of both high and low-tension mains to various contractors for town work. The instrument factory has received very large orders from the Postmaster-General and the principal railway companies, and they have to record a satisfactory increase in every department of their extensive business.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES' DIRECTORY AND HANDBOOK" is in preparation, and will shortly be published. *New names, alterations of addresses, &c., should be sent in at once.* Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, which has a special interest at the present time, is now ready, and will be forwarded on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus can be obtained on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready, and will be sent direct on receipt of the published price, 7s. 6d. (abroad 8s.), or it may be obtained from any bookseller. A prospectus will be forwarded free on application.

Digitized by Google

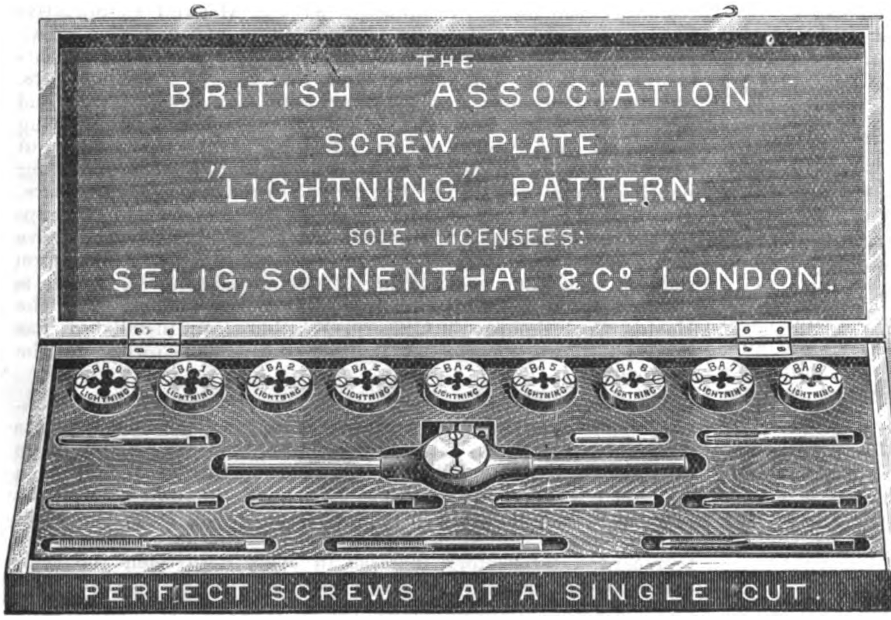
TENDERS ACCEPTED.—As stated in our last issue, the Sunderland Corporation have accepted the tender of Messrs. Hawksley, Wild and Co., for boilers, for £1,380 ; the tender of Messrs. J. H. Holmes and Co., for dynamos, at £4,640 (which will ultimately be reduced to £4,399) ; Messrs. Crompton and Co.'s tender of £1,352 for motors and alternators ; Messrs. J. H. Holmes and Co.'s tender of £575 for main switchboards and instruments. The E. P. S. Company's tender obtained the contract for accumulators at £763 ; the Silvertown Company for the cables at £2,592 ; and the British Insulated Wire Company's offer for potential leads at 10½d. per yard, amounting to about £90 ; Mr. G. E. Simpson's (of Sunderland) offer for the necessary road work obtained the order at £2,590 ; and Messrs. McLaren and Co., of Glasgow, for cast-iron work, at £290. Messrs. Doulton and Co.'s tender for the stoneware, pipes, &c., for £807, was also accepted, and other tenders agreed to include an offer for copper strip at 6½d. per pound from an English firm. The total amount of the tenders is £15,074, against an original estimate of £21,000. The whole of the tenders sent in came well within Prof. Kennedy's estimate.

——— The Fleetwood Improvement Commissioners have accepted the tender of the Brush Electrical Engineering Company (Limited) for the supply of the electrical plant for the central lighting station for the sum of £8,700. The entire cost of the installation will be £11,325.

LIQUIDATIONS.—A petition has been presented for the winding up of the Platinum Plating Company (Limited), which is down for hearing on the 11th inst.

——— A third and final dividend of 5s. is payable in the liquidation of the India-rubber Estates Company (Limited), at the liquidator's, 33, Carey-street, W.C., any day except Saturday.

BRITISH ASSOCIATION SCREW PLATE.—Messrs. Selig, Sonnenthal and Co. forward us particulars of the British Association screw plate recently introduced by them to meet a demand amongst electricians and other users of small threads. It is claimed for this plate that screws cut with it are more perfect than those cut with ordinary dies ; that they are equal to the best lathe work, and that no burr is raised above the true size. The dies have the strength and reliability of the solid die, but are not solid, being adjustable for wear so as to keep the exact size of the taps and to allow of nuts and screws for different purposes being made to fit together tightly or loosely, as desired. Accompanying the printed particulars sent are testimonials from users, who speak very favourably of the plate. The illustration shows the complete set as sold.



FOREIGN CONTRACTS. — A statement having been published that the Postmaster-General had given an order for a cable, "between Liverpool and New York," to "Siemens, of Berlin," Mr. Arnold Morley states that cables between this country and America being in the hands of private companies, the postal authorities have, of course, given no such order as above referred to, the facts of the case being that the Commercial Cable Company (as previously announced in *The Electrician*) have placed an order with Messrs. Siemens Brothers and Co. (Limited), of Queen Anne's-gate and Woolwich, for an additional cable to be laid between this country and America.

EPSTEIN ACCUMULATORS.—The Epstein Electric Accumulator Company have just completed the installation of a battery of 60 type R 11 cells for the Hunt's Bank Lighting Station of the Lancashire and Yorkshire Railway at Manchester, and the Company are very busy with a number of large battery orders, amongst which is one of 120 type R 13 cells for the Lancaster Electric Light Station, and another of 54 R 25 cells for Messrs. Barclay and Co., of Regent-street, as well as a traction set for the War Office.

MESSRS. CLAUD HAMILTON AND CO.—The Victoria Infirmary, Glasgow, has recently been completely fitted for the electric light by the above firm, the consulting engineer being Mr. T. Young, of West Regent-street. Plant and machinery to supply current to about 500 lamps have been put down.

MESSRS. NALDER AND HARRISON.—Mr. N. F. Nalder and Mr. Haydn T. Harrison have entered into partnership for the purpose of carrying on the business hitherto conducted by Mr. N. F. Nalder, and in order to cope with the increase of business they are now moving into larger premises at Trafalgar House, Great Newport-street, Charing Cross-road, London, W.C.

MESSRS. A. HALL AND CO.—Mr. G. Nicholson, trustee in the estate of the late firm of Messrs. A. Hall and Co., of Liverpool, has disposed of the goodwill and stock-in-trade of the business to Mr. L. J. Barnacle, who, with the assistance of Mr. H. H. Hall, the manager to the late firm, will carry on the business under the old name at 1 and 11, South John-street, Liverpool. The new firm are carrying out all contracts entered into by the old firm.

MESSRS. JEREMIAH HEAD AND SONS.—We are informed that Mr. Jeremiah Head has transferred his headquarters from Middlesborough to Victoria-street, Westminster, S.W., where he has taken into partnership his son, Mr. A. P. Head, M.I.M.E. The Middlesborough address will be retained as a branch office.

MESSRS. RASHLEIGH PHIPPS AND DAWSON.—This firm have secured the contract for lighting the new premises of the Bank of Scotland in Bishopsgate-street, E.C., by the electric light. Over 600 lights will be required for the installation.

CHARGE OF THEFT.—Charles Herbert Bent, the late manager of the Roundav Electric Tramway, at Leeds, was this week brought up at the Leeds City Police Court, charged with stealing £5. 12s. 8d., a suit of clothes, and other articles, the property of the Company. From the evidence of the clerk to the firm of chartered accountants employed by the Tramway Company who audit the accounts, it appears that the books were considerably in arrear, and that the cash book showed a fictitious balance. Witness further stated that there were a number of cash items paid to Mr. Bent which were not posted to any account. After some further evidence the defendant, who pleaded not guilty, was committed to the Quarter Sessions to answer the charge of falsification of accounts. Bail was allowed.

BRADFORD.—The Bradford branch of Messrs. Woodhouse and Rawson United (Limited) have recently completed an installation at the Harrogate Hydropathic Establishment, which has been lighted throughout by electricity. About 800 incandescents have been wired on the sub-circuit, with local distributing cut-out boards on each floor. The generating plant consists of two vertical engines of 12in. and 16in. cylinder, which drive two shunt-wound dynamos, so arranged that they can be run singly or together. The installation includes 60 R9-size Epstein cells.

BEDFORD.—The Electric Lighting Committee have recently replied to a communication from the Board of Trade in reference to the subject of the transfer of the Council's Provisional Order to the Bedford Electric Lighting Company, to which reference was made at the meeting of the shareholders of that Company reported in our issue of the 29th ult. The Electric Lighting Committee's reply shows that considerable difference of opinion exists amongst the ratepayers as to the proper course to be adopted by the Council.

BELFAST.—A discussion arose at the last meeting of the City Council as to the advisability of transferring the Council's electric lighting business from the Gas Committee to an Electric Light Committee (to be formed). After a heated discussion an amendment to leave the matter in the hands of the Gas Committee was adopted by 17 to 16.

BROMLEY.—Complaint is made by the local press of the dilatoriness displayed by the authorities in proceeding with the electric

Digitized by Google

lighting scheme, notwithstanding that a site has been acquired for a central station.

Buxton.—In reference to the application of the Local Board for an electric lighting Provisional Order, it has been resolved that the amount of £10,000 be fixed as the sum proposed to be expended on electric lighting.

Chelmsford.—At the last meeting of the Town Council a resolution was adopted that the contract with the electric lighting company for the lighting of the town having been renewed, the existing gas standards were no longer required, and should therefore be removed forthwith. A discussion ensued upon the clause in the Committee's report dealing with the request of the Board of Trade that the electric light wires should be put underground. The Council in committee recommended that the matter be left to the decision of the Board of Trade; but Councillor Taylor considered this would be unfair to Messrs. Crompton, who agreed that, if the Council would assist them in this matter, they would reduce the charge for private lighting from 8d. to 6½d. per unit, subject to a further discount for prompt payment. He moved, therefore, that the Board of Trade be asked to meet the wishes of the electric lighting company as far as practicable in this matter. This amendment was agreed to. With regard to the question of the purchase of the undertaking at the end of 21 years or 31 years, Mr. Fawkes stated that the electric lighting company were prepared to accept the 21 years' arrangement on the understanding that the purchase should be as a going concern, and not at a break-up price.

Drogheda.—The Drogheda Steamship Company have in hand the lighting of their stores and wharves by electricity, and for this purpose have applied for and obtained permission from the Boyne Commissioners to erect the necessary posts for the lamps.

Dublin.—Graziers and dealers in live stock who ship from Dublin are now offered the facilities of the electric light at the ports for the inspection of cattle up to 8:30 p.m. This arrangement enables owners to have their stock forwarded by the same evening's boats to England and Scotland. Four of the principal companies already use the light, and the London and North-Western Company and Messrs. Laird are shortly completing their installations.

Edinburgh.—Plans for the electric lighting plant are nearly ready, and estimates for the work are shortly to be advertised for. The probable cost of the buildings is estimated at from £10,000 to £15,000, out of a total of £80,000 to be ultimately expended.

Electric Clocks.—The Bristol branch of the National Provincial Bank of England some time ago placed an order with Messrs. King, Mendham and Co., of Bristol, to fix a clock to be electrically driven and controlled on the bank's premises. The work has now been completed.

Howth (near Dublin).—A proposal is on foot to establish public lighting in this district. It is proposed to introduce petroleum oil lamps unless some enterprising firm comes forward with a liberal electric lighting scheme.

Leeds.—The extensive goods wharf and warehouses of the Great Northern Railway Company, at Wellington-street and Wellington Bridge, Leeds, have now been entirely fitted for the electric light, which is obtained from the mains of the Yorkshire House to House Company. About 30 Brockie-Pell arcs of 1,500 c.p. are used for the out-door lighting, and the warehouses are supplied with 100-c.p. incandescents. The cable for the installation was supplied by Messrs. Siemens Brothers and Co., and the lamps, lanterns, transformers, &c., by Messrs. Johnson and Phillips. The result is that work is now carried on with much greater expedition, and with greater facility and safety.

Londonderry.—The following is taken from the *Londonderry Sentinel*:—"In reading through a seemingly inspired article in to-day's *Standard* we observe there is an insinuation that we are keeping back the completion of the electric-light works. This we strongly repudiate. Any delay that has taken place, so far as our contract is concerned, has been entirely owing to the action of the Corporation. We would have had our part of the works completed long ago had the Corporation carried out their part of the contract and put us in a position to make satisfactory progress with the works. Since commencing the contract (for reasons not known to us) we have been handicapped and made to work up-hill. Notwithstanding this, we could have given sufficient engine power at the electric station to light the whole city months ago had we been empowered to do so. Even now, if the Corporation would permit us, we could have the town engines in full working order within fourteen days.—Alex. Brown and Sons."

Leicester.—The Co-operative Society in this town have just had their extensive premises at the corner of High-street and Union-street fitted throughout with the electric light. Owing to the difficulty previously experienced in obtaining proper ventilation, the electric light was adopted, and is giving every satisfactio The plant includes a 20-H.P. Robey gas engine of the latest tern. The installation consists of about 320 lamps.

Mill Lighting.—The mills and weaving sheds belonging to Messrs. Joseph Eccles and Co., Winewall Mill, Colne, and to Messrs. N. Smallpage and Sons, Kellbrook, near Colne, have recently been lighted up throughout by electricity. In the former case power is taken from the main shaft, driving two 25-kilowatt Gardner dynamos for about 800 lights. In the latter case there are 300 lights, and the current is supplied by a 20-kilowatt Gardner dynamo driven by a Gilkes turbine. In both cases gas has been entirely superseded. The buildings are wired with a separate pilot circuit, driven by a small steam engine and dynamo. Messrs. J. E. Spagnoletti and Crookes were the contractors for the wiring and switchboards, which latter form a special feature of both installations; Messrs. Gardner and Sons, of Cornbrook, Manchester, were the contractors for the generating plant; and Mr. Harold Smith, of Colne, was the consulting engineer for both installations.

——— The large range of buildings comprising the mills of the well-known firm of Horrocks, Crewdson and Co. (Limited), at Preston, have been lighted throughout by the electric light, the work being entrusted to Messrs. J. H. Holmes and Co., of Newcastle, under the supervision of Mr. W. C. Bennett. The mills are nearly the largest in the Preston district, and the lighting is voted a great success.

Monmouth.—The Town Council have received the revised estimates of Mr. Lailey, C.E., and the Brush Company, showing the cost of draining and electric lighting separately. The tenders together amount to £19,040, and a special meeting was called for yesterday (Thursday) to consider the matter.

Morley.—The Town Council have carefully considered several schemes placed before them for lighting the town and municipal buildings by electricity, and it has been decided to consult an electrical expert on the matter. The Council are to visit such London and provincial lighting stations as they consider advisable.

Reading.—A local company will shortly be formed for the purpose of carrying out a comprehensive electric lighting scheme. Mr. F. F. Yeatman, manager of the electric supply station at Reading, announces that arc lighting is increased in the town by 4 per cent., while the number of incandescents to which current has been supplied during the past year has trebled.

Sheffield.—Many of the business premises in this town have been supplied with electric current from the mains of the Sheffield Electric Light and Power Company, and the extension into residential suburbs, especially Ranmore, is in contemplation.

Ship Lighting.—Messrs. Laird Bros. have just launched from their works at Birkenhead a twin-screw torpedo cruiser, built for the Argentine Government, named the "Patria." The vessel is supplied with complete duplicate sets of electric lighting plant.

Sutton (Surrey).—The Local Board have discussed the question of advertising for tenders for lighting the district by electricity. Several local firms who have been approached have declined to tender, expressing their willingness to take the matter up should there be any difficulty experienced in obtaining suitable tenders. The matter has been, after some discussion, referred back to the General Purposes Committee.

Wigan.—A very serious deterioration of the books in the Free Library having occurred, it has been pointed out to the Gas Committee that not only is the lighting in the library insufficient and unsatisfactory, but that the safety of a very valuable collection of books was placed in jeopardy. The Library Committee, therefore, asked that a system of electric lighting shall be adopted forthwith.

Works Lighting.—At the beginning of the winter the Cart Vale Chemical Company decided to put down an electric lighting installation, the work for which was entrusted to Messrs. Robertson and Co., of Paisley. Seven 2,000-c.p. arcs have been fitted up, the plant including a Woodside dynamo and a 12-H.P. steam-engine.

——— The extensive works of Messrs. Dickson and Mann (Limited), at Armadale, Scotland, have recently been fitted throughout with the electric light, including the engineering, bridge building, and steel tool-making departments. The work was carried out by Messrs. Walter Dixon and Co., of Glasgow.

Yalding (near Maidstone).—In reference to our "Note" last week, we are informed that the Cheveney installation was completed in December, 1892, and that Messrs. B. Verity and Son erected the whole of the work, which has continued to give the greatest satisfaction from the start.

Annual Dinner.—The past and present pupils connected with the Manchester branch of Messrs. Woodhouse and Rawson United (Limited) held their first annual dinner on the 20th ult., at the Grosvenor Hotel, Manchester. A pleasant evening was spent.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

December 9, 1893.

23,744. R. J. Urquhart. Manchester. Improved method of, and appliances for, lighting railway trains by electricity. (P. de Y. Ysasmendi, Spain.)*

December 12, 1893.

23,857. D. Cook. Richmond. Apparatus for generating electricity.

23,862. E. H. South. London. Improved means for the automatic regulation of the position of the brushes of dynamo-electric machines and electro-motors.

23,881. W. P. Thompson. Liverpool. Improved method of, and apparatus for, heating metals electrically. (C. L. Coffin, United States.)*

23,897. C. J. Reed. London. Improvements relating to electric signalling or the transmission of information and energy by electricity, and to apparatus therefor.*

23,902. W. P. Hall. London. Improvements in and relating to electric motors.*

23,913. R. Haddon. London. Improved process and apparatus for dissociating soluble salts by electrolysis. (H. S. Blackmore, United States.)*

23,914. J. A. Bisson. London. Improvements relating to the insulation of submarine and other electric cables.

December 13, 1893.

23,951. T. Bassnett. Liverpool. Telegraphic apparatus.

23,962. A. C. Hewitt and G. W. Pyke. Maidenhead. An electric fire-escape.

24,001. J. Coombes. London. An automatic thermo-electric lubricating apparatus. (R. N. Coombes, Western Australia.)

24,017. E. Stouls. London. Improvements in or relating to processes and apparatus for obtaining and depositing metals by electrolysis, and in the treatment of the metals after leaving the electrolytic bath.

December 14, 1893.

24,035. G. Combe and Siemens Brothers and Co. (Limited). Halifax. A combined regulating switch, and motor for actuating same.

4,055. J. H. Cooper. Limerick. A means of governing or controlling automatically the electric current generated by a dynamo or electric generating machine.

24,081. R. Niewerth. London. Improvements in the manufacture of carbon for electric lighting and other electric purposes.

24,104. R. D. Ratcliffe. London. Improved combined tidal motor, dynamo-electric generator and storage batteries.

December 15, 1893.

24,111. A. D. Lagrelle. London. New or improved means for applying electricity for warming the seats of water-closets, close-stools, and the like.

24,131. M. A. Mosley, R. Wright, and J. H. Richardson. Bradford. Improvements in, or appertaining to, the electro-deposition of zinc.

24,154. R. L. Grahame and E. S. Cadman. Teddington. Improvements in electrical guides or indicators, and batteries therefor, specially applicable for carriages and the like.

December 16, 1893.

24,217. W. E. Ayrton and T. Mather. London. Improvements in electrical measuring instruments and apparatus for use with alternating currents.

24,234. A. C. Cossor. London. Improvements in the manufacture of filaments for incandescent lamps.

24,241. H. Weymersch and E. Freund. London. Improvements in primary batteries.

24,243. W. H. Lander. Dublin. An improvement in electrical arc lamps.

24,254. F. H. Nalder, H. Nalder, C. W. S. Crawley, and A. Soames. London. Automatic switch.

24,271. C. Bonnard and F. A. Piat. London. Improvements in and connected with telephonic apparatus.*

24,274. C. Kellner. London. Improvements in apparatus for the electrolytical decomposition of metallic salts.

24,276. H. Guthrie. London. Improvements in apparatus for electrolytic purposes.

24,285. H. Edmunds. London. Improvements in means for connecting or supporting electroliers, brackets for electric lamps, or the like, to or from ceilings, walls, or other places of support.

December 18, 1893.

24,295. H. F. Hoveler. London. Improvements in elements for secondary and other electric batteries, and in the manufacture of same.

24,344. J. A. Kingdon. London. Improvements in dynamo-electric machines.

24,353. C. K. Mills. London. A new or improved preparation of active material for electric accumulators. (C. J. Barbier, France.)

December 19, 1893.

24,389. A. Lehmann. Glasgow. Improvements in electrode plates for secondary batteries.

24,392. C. F. Winkler. Manchester. Improvements in and connected with electric motors for vehicles.

24,409. H. Bonser. London. Improvements in or relating to means for conveying electrical currents to the workings of coal and other mines.

24,414. W. P. Thompson. Liverpool. An improved means of underground current supply for electric railways. (A. Rast, Germany.)

24,417. J. B. Torres. London. Improvements in electric or galvanic batteries.

24,442. C. K. Mills. London. A new or improved electrical accumulator plate. (C. J. Barbier, France.)

24,446. W. A. Phillips. London. Improvements in electric lamps. [Date applied for under Patents, &c., Act, 1883, Sec. 103, June 3, 1893, being date of application in United States.]

December 20, 1893.

24,471. W. Thomson (Baron Kelvin). Glasgow. Improvements in electricity supply meters.

24,472. J. T. Bottomley. Glasgow. Apparatus for evaporation, distillation, or concentration of liquids by means of heat produced by an electric current.

24,517. F. J. Mockler. London. An improved advertising reflector for the top of electric light globes.

24,557. A. A. Common. London. Improvements in or relating to electric printing or signalling apparatus.

December 21, 1893.

24,606. E. A. Claremont. Manchester. Improvements in the means of suspending arc and other electric lamps and fittings.

24,607. E. A. Claremont. Manchester. An improved insulated lever for use in electrical switches and other like appliances.*

24,608. E. A. Claremont. Manchester. Improvements in the construction of, and in the means for fixing, flywheels to the pulleys of dynamo-electric motors and generators.*

December 22nd, 1893.

24,730. F. G. S. Curtis. London. Means for use in combination with conduits or conductors for the supply of gas or other fluid, or of electricity, for indicating the time during which such gas or other fluid or electricity has been consumed.

December 23, 1893.

24,736. J. Whitaker and T. P. Pollitt. Manchester. Improvements in electric bells.

24,751. J. S. Raworth. London. Improvements in safety appliances for use in connection with generating and distributing apparatus for high-pressure electrical currents.

24,757. W. Arnold and W. Crowther. Halifax. Certain improvements in electric apparatus for stopping steam or other engines.

24,771. F. V. Andersen. Catford. Improvements in electrical measuring instruments.

24,790. R. E. B. Crompton. London. Improvements in brush-holders for dynamo-electric machines.

December 27, 1893.

24,864. E. Thomson. London. Improved methods and means of compounding dynamo-electric machines.*

24,865. H. H. Lake. London. Improvements in insulators for electric wires. (W. B. Bond, United States.)*

24,867. J. C. Love and A. G. Wheeler. London. Improvements in electric railways.*

24,871. H. T. Johnson. London. Improvements in dry batteries.*

24,911. T. J. Dewees. London. Improvements in electric cables and in the method of making the same.*

SPECIFICATIONS PUBLISHED.

All Specifications price 8d. each.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, &c., &c.]

CAPE ASBESTOS COMPANY (LIMITED).—This Company, which was registered on December 28, 1893, with a capital of £55,000, in £1 shares, in addition to the acquisition and development of certain lands containing asbestos in Griqualand West, includes the manufacture and sale of india-rubber, gutta-percha, caoutchouc, and all kinds of vulcanised and elastic goods, including telegraph and telephone wires and cables, tubing, pipes, &c.

COWLISHAW, WALKER AND CO. (LIMITED).—This Company was registered on December 30, 1893, with a capital of £10,000, in £10 shares, to carry on the business of general engineers, iron and brass founders, millwrights, boiler makers, machinists, &c., carried on by Cowlishaw, Walker and Co.

FROGGATT'S INVENTIONS SYNDICATE (LIMITED).—This Company was registered on January 1st, with a capital of £1,000, divided into 500 Ordinary and 500 Preference shares of £1 each, to purchase or otherwise acquire in any manner or for any term certain letters patent, patent rights, inventions, and processes for the generation and storage of electricity granted to or invented by Thomas Froggatt and others, and to carry on the business of electrical engineers and fitters, manufacturers of and dealers in electrical accumulators, lamps, and other electrical apparatus, contractors for the supply of electrical energy, for lighting, heating, and other purposes, suppliers of electricity, &c. The subscribers (with one share each) are William Price, Sydney Howarth, John Martin, Robert C. Page, Arthur Hampson, Benjamin Brancher, and Thomas H. Derbyshire, all of Liverpool.

JOHN LAMPITT AND CO. (LIMITED).—Capital £6,000, in £25 shares. General engineers, ironfounders, boiler makers, brassfounders, millwrights, and agricultural implement makers, of Banbury.

ARIEL COMPANY (LIMITED).—The statutory return of this Company made up to December 14, 1893, has been filed. The nominal capital is £15,000, divided into 1,000 Preference and 2,000 Ordinary shares of £5 each. 670 Preference and 2,000 Ordinary shares have been taken up, of which 400 Preference and all of the Ordinary shares have been issued as fully paid. Upon 50 Preference the full amount has been called, while upon the remaining 220 a call of £3 per share has been made, resulting in the payment of £910.

BEDFORD ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to December 27, 1893, has been filed. The nominal capital is £15,000, divided into 250 Founders' and 14,750 Ordinary shares of £1 each. 154 of the former and 882 of the latter have been subscribed for and allotted. Upon the Founders' shares the full amount has been called, while upon the Ordinary shares a call of 1s. per share has been made. The calls paid amount to £197. 19s., leaving 3s. in arrears.

LAMINA ACCUMULATOR (ELIESON'S BRITISH PATENTS) SYNDICATE (LIMITED).—The statutory return of this Company, made up to November 8, 1893, has been filed. The nominal capital is £12,000, in £1 shares, of which 4,007 have been taken up. Upon 3,757 of these a call of 3s. per share has been made, resulting in the payment of £563. 10s., and leaving £376. 15s. in arrears, while the remaining 250 shares have been issued as fully paid. The 6,000 shares which the vendors were to receive as their purchase consideration have not yet been allotted, the 250 shares mentioned above being the price paid to Moritz Immisch for certain electrical apparatus in connection with the patents of that Company.

UNIVERSAL ARC LAMP SYNDICATE (LIMITED).—The first annual return of this Company, made up to December 20, 1893, has been filed. Out of a nominal capital of £3,000, in £1 shares, 2,865 have been taken up. On these a call of 1s. 6d. per share has been made, resulting in the payment of £228. 15s. Holders of 15 shares have paid the full amount of £1 upon their shares.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—The annual return of this Company, made up to December 7, 1893, has been filed. The whole nominal capital of £70,000, in £1 shares, has been taken up, of which 56,506 have been issued as fully paid, and the full amount paid on the remaining 13,494 shares.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended December 31st were £833, as against £966 for the corresponding period of last year, being a decrease of £133. The total receipts for the half-year amount to £21,820, as against £21,786 for the corresponding period of 1892, an increase of £34.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY.—Mr. H. G. Massingham has resigned his position as Director of this Company, owing to his having taken up his residence at Taunton.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of December are £3,700, as compared with £3,693 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH.—Estimated receipts for the month of December £1,895, against £2,092 last year.

DISTRICT MESSENGER SERVICE AND NEWS COMPANY (LIMITED).—At the ordinary general meeting of this Company the Chairman said their business progressed steadily and materially. For the first month—July, 1890—the takings were £1. 7s. 6d.; in July, 1891, they were £566; in July, 1892, they were doubled, amounting to £1,201; and in the month of July, 1893, they reached £1,607, since which date they had steadily increased. The British public were slow to move, and required time to take to a new enterprise. There were hundreds and thousands of people in London who had never heard of their system.—Mr. Campbell Praed said they were weak as regards working capital; when the balance-sheet was referred to the results attained during the last year were very satisfactory.—Mr. C. T. Russell (managing director) said that, notwithstanding the bad times and the many causes operating against the success of the system during 1893, the revenue had steadily increased, with but very little increase in the working expenses. The revenue derived from messenger service last week was £470, which exceeded that of the corresponding week last year by £105, and, in fact, exceeded any week since the inception of the Company. Out of 11,400 boxes installed 1,700 were paying a yearly rental of one guinea. As no boxes are now installed without a rental this item alone would go far towards paying a dividend for the ensuing year. The Company had received very little benefit from the amalgamation with the Boy Messenger Company; the expenses connected with the taking over the wires, call-boxes, offices, &c., had been a constant drain upon their revenue and resources. Eventually, the Company would derive substantial benefit in consequence of this amalgamation; to equip them they were operating some of their offices at a loss on account of want of sufficient capital. The Directors had decided to issue £40,000 of cumulative Six per Cent. Preference shares, to enable them to complete these offices and to pay off the debenture bonds, thereby saving a fixed charge of about £1,600 per annum. The Company was actually paying its full running expenses. Their system had become one of the institutions of London. While it has been a plant of slow growth, necessarily, from the nature of the business, it has become a splendid property. A continuous increase in the sale of the Company's coupons had taken place, amounting now to upwards of £60 per month, and the Directors have it under consideration to make a reduction to all tradesmen purchasing coupons. Another source of revenue had been created by placing a modest charge of 5s. upon all the call-boxes installed in the City, amounting to upwards of 5,000. He regretted to say that the Postmaster-General showed no desire to rebate any portion of the enormous tax placed upon the Company. They were not only taxed 1d. on each letter, but the nucleus of their business is also burdened by a tax of 2s. 6d. on every electric call-box, the total payments amounting to 12½ per cent. on the entire gross receipts.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of December amounted to £55,579, as against £59,776 in the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of December amounted to £36,906, as against £42,295 in the corresponding period of 1892.

MEDICAL BATTERY COMPANY (LIMITED).—A winding-up order was made against this Company on November 22nd last, and a statement of affairs has now been submitted, accompanied by the observations of the Official Receiver and Provisional Liquidator (Mr. C. J. Stewart). The gross liabilities are returned at £23,916, of which £19,780 will probably rank, with assets £4,242. The total deficiency as regards contributories is stated to be £119,780. The Official Receiver asserts that the claims of unsecured creditors (£15,766) comprise claims for advertising and printing £13,867, and goods supplied £1,879. The machinery, valued as an asset, at £1,000, consists chiefly of mechanical appliances for the Zander method of treatment of disease, and cost the Company £10,777. A summary of Mr. Stewart's report and a general statement of the affairs of the Company will be found in our issue of the 15th ult.

NEW PANULCILLO (LIMITED).—This Company is formed for the purpose of acquiring from the liquidators of the Panulcillo Copper Company the mines and smelting works, with a view to developing them and working them in a more vigorous and economical manner than hitherto. The capital is £50,000, in £1 shares, payable 5s. on application, 5s. on allotment, and the balance in sums of 2s. 6d., at not less than one month's notice. The Directors are Sir John Pender, G.C.M.G., M.P., Mr. F. J. Johnstone, Mr. J. Denison Pender, and Mr. R. S. Archbold

Digitized by Google

The Secretary and offices are Mr. W. Leigh Hunt, 3, Great Winchester-street, London, E.C. The subscription list closes for London at 4 p.m. on Tuesday next, and for the provinces and abroad by first post on Wednesday morning.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended December 29th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £2,719.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 817.—Vol. XXXII. FRIDAY, JANUARY 12, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The loss that science has suffered by the untimely death of Prof. Hertz is feelingly expressed in another column by Dr. Oliver Lodge, who went so near to anticipating the discovery of those electro-magnetic oscillations which will for all time be inseparably linked with the name of Hertz. In the modesty and self-forgetfulness which blend so admirably with the spirit of true scientific research Hertz was singularly rich. A letter that we received nearly four years ago from Prof. Hertz in answer to a request for permission to publish a portrait of him has pathetic interest at the present moment, and is a striking instance of his invincible modesty:—

Bonn, June 22, 1890.

Dear Sir: You will oblige me very much by postponing for a year, or better, for two years, the kind intention you have in respect to my portrait. I feel as if presenting my portrait now in so prominent a place rather follows too quickly the little work I have done. I should like to wait a little, and see if the general approbation which my work meets with is of a lasting kind. Too much honour certainly does me harm in the eyes of reasonable men, as I have sometimes occasion to observe. If your kind intention is the same in two years, or even one year, I shall readily consent and help you in every respect. With many kind thanks, and the assurance that I feel only too much honoured, Yours truly, H. Hertz.

On Thursday last week, as was recorded in our "Notes" columns, the Brighton Corporation decided to purchase the business of the Brighton and Hove Company for the modest sum of £5,000—a sorry ending to a venture of no little technical and historical interest. Starting in the autumn of 1881 with an arc-light station, the Brighton Company's business developed under Mr. Arthur Wright into a station on the constant-current multiple-series system with over 1,500 lamps connected to its wires, and finally into a 10,000-light station on the house-transformer system. Notwithstanding all the ingenious devices by which Mr. Wright succeeded in making a tolerable success of so troublesome and impracticable a system, his hard work, in more than one direction, was destined to be thrown away. Not only is the constant current—an ill-advised choice from the beginning—extinct, but even when alternators and house-transformers were used, the success of this "pioneer" supply was not remarkable.

Twelve years ago the first Electric Lighting Act was *in futuro*, and municipalisation was not very much in evidence; had it been so, to have started an electricity supply business without previously obtaining the support, or, at any rate, the benevolent neutrality of the Brighton Corporation, would have been then as wild a speculation as such a course would undoubtedly be to-day. On the other hand, the Brighton Corporation has not been entirely without mercy, since it gives £5,000 for an undertaking which would, in all probability, have ultimately passed into its hands for nothing. The *Sussex Daily News* argues that the Corporation will get 11¾ per cent. on the purchase-money; so it will, but when we add the £19,000 fresh outlay that will be needed before the Company's present customers can be supplied from the Corporation station, Mr. Wright's estimated net revenue becomes 2½ per cent. on the capital expended, which is scarcely an extravagant return.

Monday last was a somewhat stirring day from the point of view of accidents connected with electrical conduits, mishaps having occurred in places as far apart as Newcastle-on-Tyne, London, and Bournemouth. At Newcastle a telephone repairer was endeavouring to thaw the ice which had collected on the lid of a street-box, when an explosion occurred, slightly injuring the man. In London, at the top of Ludgate-hill, some men belonging to the City of London Electric Lighting Company were opening the ground near a fire that they had kindled, when there was an explosion, resulting in the lifting of a couple of manhole covers and the injury of a small boy.

Hitherto the only mystery attaching to these electric-light main explosions has been due to the difficulty of accounting for the fatal spark, the necessary materials for mischief being admittedly ready at hand in the leakage of coal-gas from the gas mains into the electrical conduits. But at Newcastle and Ludgate-hill, however, there is no need to start ingenious hypotheses as to why electrical mains should suddenly betake themselves to sparking; the determining cause was present in each instance in the shape of an ordinary every-day flame.

Electric lighting seems destined to act the part of standard-bearer to the gas industry. The introduction of the glow lamp and arc lamp has led to the invention of the incandescent gas lamp, Wenham lamp, and many another improved burner. And now these too frequent street eruptions, supplemented by the pressure of adverse legal decisions (*vide* "Loveland *v.* Gas Light and Coke Company") seem likely to result in improved methods of laying and jointing gas pipes. On the other hand, the fact that gas manages to find its way into the electric light conduits is a proof that these, too, leave room for improvement. Sydney Smith was of opinion that our railway companies would never refrain from their detestable habit of locking their passengers in until a train caught alight, and a sealed-in Bishop got burnt. We trust that the

Digitized by Google

two industries which are severally responsible for these little interruptions to the placid continuity of City life will not wait until the Dean of St. Paul's is blown up before they apply a drastic remedy.

THE accident at Bournemouth was of a different character to either of the preceding ones. As a two-horsed omnibus was drawing up at the Imperial Hotel, both horses suddenly fell down. One expired immediately, but the other was dragged away alive, all those assisting receiving slight shocks. Subsequently it was noticed that other horses on passing the spot, which was exactly over one of the iron-and-brick electric light chambers, kicked and plunged. The Electric Light Company was telephoned to, and on the mains connected to the hotel being cut off, the phenomena ceased. On Tuesday Major CARDEW was sent down at the instance of the Bournemouth Town Council to investigate the matter; the mains were tested by a battery, but no leak was revealed. It may be mentioned that three veterinary surgeons who made a *post mortem* on the unfortunate horse agree that it met its death through an electric shock. That electricity was the cause of this mishap there seems, therefore, to be no reasonable doubt, and that Major CARDEW was unable to discover an "earth" by means of a battery need not make a mystery of the matter; a 2,000 volt test, backed by a few horse-power, would probably soon do that. Major CARDEW's report to the Board of Trade will no doubt make the cause of the accident quite plain.

THE attempt to meddle with the standard candle having failed, a proposal is now made to relax the 16-candle quality of London gas. The public are told that it costs about 2d. per thousand cubic feet to doctor up the gas with cannel, petroleum, or other "enrichment," and that a gas of fourteen to fifteen candle-power, "if used with proper burners," would give at least as good light as consumers are getting now. Those "suitable burners" are an old trick. No comparison is ever made between electric light and gas, by gasmen, where the beloved London Argand burner is not used, if the muddle by Mr. TERRACE be excepted. We hope that the report on tests of gas burners, which we recently published, thoroughly exposed this artifice. The consumers of the South Metropolitan Gas Company are assured that the change will put £20,000 to £30,000 a year into their pockets. Will the Company have no corresponding profit? Who is going to pay for these "proper burners"? The Company, surely.

New Year's Honours.—Amongst the recipients of New Year's honours was Mr. W. R. Brooke, Director-General of the Indian Telegraph Department, who was made a C.I.E.

Newport (Mon.).—On Wednesday last week Col. John Ord Hasted, R.E., Local Government Board Inspector, held an inquiry into the application of the Newport Corporation for a loan of £28,000 for the purposes of electric lighting.

Madrid.—We have received a letter from the Electricity Supply Company for Spain, informing us that the paragraph in our issue of December 29th, relating to that Company, stating that a war of rates had broken out between them and the German Company, is "very inaccurate."

Obituary.—The death is announced of Herr A. Steinheil, who in 1851 organised the Swiss telegraph system, after having served his time in the Bavarian telegraph service. Herr A. Steinheil was a son of the famous Steinheil who discovered the "earth-return."

The Hermite Electrical Sanitation Process at Worthing.—Worthing is about to be the scene of some experiments in sewage disinfection by means of electrolysed sea water, the Town Council having voted a considerable sum of money to enable M. Hermite to get to work during the present month to demonstrate the value of his system.

Electric Traction in the Hartlepools.—A deputation went last week from the Hartlepools to Leeds for the purpose of inspecting the electric tramcars. It is proposed to utilise the existing tram lines between the Hartlepools for electric cars, a syndicate having been formed with that view. The Mayors of the two boroughs accompanied the deputation.

The Telegraph Revenue.—The receipts from the telegraph service for the quarter ended December 31, 1893, amounted to £620,000, as against £615,000 for the corresponding period of 1892. The receipts for the period, April 1 (1893)—December 31 (1893), amount to £1,955,000, as against £1,925,000 for the corresponding period; an increase of £30,000, or ·15 per cent.

Cable Interruptions and Repairs:

	Date of Interruption.	Date of Repair.
San Domingo-Martinique	Dec. 10th, 1893	Jan. 8, 1894
Cayenne-Paramaribo	Oct. 25th, 1893	—
Cayenne-Vizeu	Nov. 25th, 1893	—
Lagos-Brass	Dec. 4th, 1893	—
Haiphong-Hongkong	Dec. 11th, 1893	—
Garachico-Santa Cruz de Palma	Dec. 27th, 1893	—

The Home Office and Accumulator Works.—The *London Gazette* of Friday contains a declaration by the Home Secretary, under the Factory and Workshop Acts, to the effect that the following processes carried on in factories or workshops are dangerous or injurious to health:—The manufacture of red, orange, or yellow lead, lead smelting, the tinning and enamelling of iron hollow ware, electric accumulator works, flax mills and linen factories.

Electric Traction at Liége.—An overhead trolley line, about two miles long and with a maximum gradient of 3½ per cent., has recently been opened between Liége and Herstal. The pressure is 550 volts, and the cars, which weigh about a ton and seat 32 people, are fitted with one 25-H.P. motor, each worked with single reduction gearing in the ratio of 1:5. The plant is of local origin, and much of the experience of American engineers appears to have been disregarded in the construction of the line.

Electrical Properties of Thallium.—In a Paper read before the Royal Society of Victoria last month, Mr. W. H. Steele describes his researches on the physical constants of thallium. Mr. Steele gives, as the specific electrical resistance of this element, 20,200 C.G.S. units at 20°C., with a coefficient of variation of resistance of 0·00392 in the neighbourhood of this temperature. He also finds that the absolute thermo-electric height of thallium is $(216 - 0{\cdot}79\theta)$, where θ is the temperature on the centigrade scale. The coefficient of linear expansion with rise of temperature was found to be 0·0000225 per 1°C.

Electric Tramways on the Continent.—The Halle Tramway, although its extension has only been nine months at work, pays 7½ per cent. dividend. The Breslau Tramway has been working since June; the Essen Tramway has been running since the end of August; the Kieff Tramways are all to be changed into electrically-driven roads. Electric traction is being started also at Chemnitz, Dortmund, Lübeck, and Christiania. All the above undertakings have been, or are being, carried out by the Allgemeine Elektricitäts-Gesellschaft. The Leipzig Town Council have published a specification for an electric tramway in certain parts of the town, on the basis of a 40-year concession.

Electrical Typewriting Machine.—An electrically-operated typewriter, says the *Engineering Magazine*, has been for some time in use in Boston, which is so arranged that it may not only be used in the ordinary manner for office correspondence and copying, but may be electrically connected with a similar instrument at a distance, so that a copy of the work may be

Digitized by Google

automatically reproduced thereon, even in the absence of an attendant. In its long-distance action it has been anticipated, of course, at any rate in principle, by Prof. Hughes' type-printing telegraph. But, in the office, if the instrument is more silent than its mechanically-operated prototype, it ought to find a ready welcome. A silent writing machine, which could be run off a 100-volt lighting circuit, would be a great boon.

Electric Motors on H.M.S. "Centurion."—On Thursday morning last week the first-class battleship "Centurion" went through her gunnery trials at Portsmouth. The "Centurion" is interesting as being the first battleship in the Royal Navy in which electric motors will be made use of, in a very tentative manner it must be confessed, to assist the working of heavy guns. It is intended to fit electric-motors to the elevating apparatus, designed for a large angle of fire, viz., minus 7deg., plus 35deg. elevation. The loading station being almost horizontal, the electric motors will be valuable adjuncts to the hand-elevating appliances when the guns have to be moved through the angle from loading position to maximum elevation cr thereabouts. The motors, however, are merely auxiliaries, as the elevation can be accomplished by the manual gear, though less expeditiously. An electric motor is also being fitted to the upper hoist for rapid transport of the charges to the guns.

German Central Stations.—The following table of statistics is of use for purposes of comparison, and is taken from the *Elektrotechnische Zeitschrift*:—

Station.	Years in work.	Output B.T. units.	Percentage of energy sold to energy produced.	Cost of coal pr.B.T. unit.	Works costs per B.T. unit sold.	Hours pr. day per lamp.	Profit in percentage of capital outlay.
Barmen	5	122,026	84·2	0·685	2·98	2·48	7·65
Cologne	1	307,074	...	0·81	...	2·67	6·62
Dusseldorf...	1	337,285	69·7	0·41	1·63	3·10	10·85
Elberfeld ...	5	305,794	97·5	0·85	2·88	2·29	14·09
Hamburg ...	4	513,183	94·5	1·20	2·53	3·09	18·05
Hanover	2	365,114	80·7	0·48	2·09	2·56	11·34

Copper.—According to Messrs. Stedman, Crowther and Co.'s metal report for 1893, copper was at its highest in January, the price being £46. 12s. 6d. at the beginning of the year. The price then fell almost continuously until it touched £42. 15s. by the end of May. After a rise to £45. 2s. 6d. in June a decline again set in, and in August, £40. 12s. 6d., the lowest price of the year, was reached. A good deal of buying, both for consumption and speculation, was induced by the low price, and the value improved £2. 10s. by the middle of September. The available stock has now been falling month by month almost without a break since April, 1889, nearly five years; and, although there was an increase in the world's annual production of over 40,000 tons in the same period, this was absorbed, and an additional 70,000 tons from stock. Putting 1889 (when consumers' stocks, abnormally small during the reign of the syndicate, had to be filled up) out of the question, there still remains a reduction in stocks of 48,500 tons during the last four years, *i.e.*, from 95,700 tons on January 1, 1890, to 47,295 tons on January 1, 1894.

Wolverhampton.—On Thursday, last week, Mr. Codrington, one of the Local Government Board inspectors, held an inquiry at Wolverhampton, relative to an application for a loan of £30,000, for the purpose of carrying out an electric lighting scheme in the borough. The Town Clerk said the Provisional Order was granted in August, 1890. The central switch station would be at the Town Hall, with branch stations at the Art Gallery and the Free Library. The estimated cost of the scheme was £30,000, of which £17,442. 14s. 2d. was for plant, and £1,320 for arc lamps, and £2,243 would be left for contingencies. With regard to the question of the repayment of the loan, he had written to the Local Government Board asking whether they had any powers to suspend the operation of the sinking fund with respect to this undertaking for a few years, in order to enable the Corporation to turn round during the time between the commencement of the work and the completion of it. It was not to be supposed that the Corporation would make instant profit. The electrical engineer estimated the dead annual expenditure at £3,307, and to cover this a minimum annual consumption would be required of 193,600 units at 6d. per unit.

Electric Propulsion of Canal Boats in France.—On the canal between the Seine and the Saône there is an interesting application of electric power to the propulsion of canal boats. It occurred to M. Galliot, an engineer at Dijon, to utilise the water power of the fall of water at the lock sluices to drive turbines and dynamos for this purpose. This scheme is now actually realised, and an efficiency of 30 per cent. between the turbines and the canal boats is said to be attained. The turbines are placed on the falls with their spindles vertical, and are each capable of developing from 15 to 20 H.P. The vertical shaft of the turbine is geared by bevel wheels into the horizontal shaft of a dynamo. The electric power is conveyed along the canal by means of a phosphor-bronze overhead line, 8mm. in diameter. Each towing boat is provided with a motor, which is driven by power taken from this trolley line. In addition to working the canal boats, the electric power is partly utilised to light up the interior of a length of tunnel through which the canal passes. The propulsion of the towing boat is effected, not by means of propellers on the boat itself, but by a train of gear wheels connecting the motor to a chain which extends along the bottom of the canal, and by means of which the boat drags itself along.

The Telegraph in Zambesia.—In the course of a lecture on "The Capabilities of Zambesia for Commercial Expansion and Development," delivered by Mr. Archibald R. Colquhoun (the first Administrator of Mashonaland), on Monday, before a meeting of the London Chamber of Commerce, the lecturer said:—"The telegraph is now being carried northwards towards Zambesi, to form connection later with Nyassaland, joining all the lakes, and eventually linking on the Cape to Cairo, an important project planned by Mr. Rhodes, which has been pronounced rather visionary. I hold it, however, to be perfectly practicable. In a country like Zambesia the telegraph must be the precursor of roads and railways, as it has been in Persia and China, where there were, and still are, practically, no roads and no postal communication. In those countries an enormous volume of correspondence and business is done by the wire, which replaces the postal service of Europe. The laying down of communications varies with the conditions of the regions; for instance, in Europe the railways follow the roads, because we had roads; in America the country is covered with railways and telegraphs, while there are virtually no roads even now; in Asia and Africa the telegraph naturally comes before, or simultaneously with, the railway."

Distribution of Electric Stress in the Higher Regions of the Atmosphere.—A recent number of the *Comptes Rendus* contains a note, by M. André, on the variation of the electric state of the high regions of the atmosphere in fine weather. During a previous attempt to investigate this point, the author unfortunately met with an accident which has prevented him personally making any more observations; the measurements contained in this note have, however, been made under his directions. At opposite corners of the car of the balloon were fixed two cylindrical reservoirs, filled with distilled water, and insulated on plates of sulphur. To the base of each of these vessels an india-rubber tube, about 20 metres long, was attached, each tube having a small jet at its end. When the balloon had come to rest at any desired height, the difference of potential existing between two points, at a known vertical distance, was determined by means of an Exner electrometer connected metallically with the water reservoir. This difference of potential, the distance being kept constant, gave a measure of the strength of the electrical field. As a result of two series of observations, the author considers that in fine weather the strength of the electrical field does not increase with the altitude, but is the same at a given instant at any point along the same vertical.

Franklin Institute.—The Committee on Science and Arts of the Franklin Institute request us to bring to the notice of our

Digitized by Google

readers the character and conditions of the awards at their disposal:—The Elliott Cresson Medal, founded in 1848 by the gift of the late Elliott Cresson. This medal is of gold, and by the terms of the deed of trust may be granted for some discovery in the arts and sciences, or for the invention or improvement of some useful machine, or for some new process, or combination of materials in manufactures, or for ingenuity, skill or perfection in workmanship.—The John Scott Legacy Premium and medal (twenty dollars and a medal of bronze), awarded by the City of Philadelphia. This medal was founded in 1816 by John Scott, a merchant of Edinburgh, Scotland, who bequeathed to the City of Philadelphia a considerable sum of money, the interest of which should be devoted to rewarding ingenious men and women who make useful inventions. The premium is not to exceed twenty dollars, and the medal is to be of copper, and inscribed "To the most deserving."—The Edward Longstreth Medal of Merit, founded in 1889, by Edward Longstreth, machinist, and late member of the Baldwin Locomotive Works. This medal is of silver, and may be awarded for useful invention, important discovery, and meritorious work in, or contributions to, science or the industrial arts. Full directions as to the manner and form in which applications for the investigation of inventions and discoveries should properly be made will be sent to interested parties on application to Mr. William H. Wahl, Secretary, Franklin Institute, Philadelphia, Pa., U.S.A.

Braking and Trolley Accidents.—In view of the outcry which has been raised against the inefficient system of braking electric cars in America, Mr. McFarlan Moore makes the following criticism:—"Even with the present methods of electric street-car control, accidents will soon become less frequent than on horse-car lines during the past. Many of the communications in both the daily and electrical papers lead one to infer that the present list of accidents is to continue indefinitely, unless the present methods of car control be radically improved. This is a mistake. The cause of nine-tenths of the accidents so common at present is due entirely to the forgetfulness of the general public that trolley cars run at a much higher speed than the horse cars. The utter nonchalance with which even ladies allow the noses of car horses to graze their shoulders, proves that the many years of slow-moving transit has formed a habit much too strong to be entirely broken in a few months. Rapid transit must be *rapid* and the public will learn, perforce, that more time allowance must be made when crossing the tracks ahead of the modern trolley car. In the very nature of things there must be a limit to the *practical* length of time required to bring a rapidly-moving car to rest, and the comfort of the passengers, for whom the car is run, must not be overlooked. The education of the public in this matter is the only solution to the problem of preventing street-car accidents on trolley lines. The history of the past indicates that surface rapid transit in cities has come to stay, and in the future the public will enjoy even greater speed than is now in vogue." This is very much to the point; for while it is quite necessary to provide a swifter car with a more powerful brake, it is absurd to expect that the swifter car can be pulled up or slowed down in the same number of yards as a slower one. There is a certain amount of acceleration in starting and stopping a car, beyond which it is dangerous to the passengers to go, and the limit of this rate of change of speed is not greater for rapid transit than for ordinary transit.

Artificial Leaks on Land Lines.—In an article on "Self-induction as a Remedy for Static Discharge," in a recent issue of the *Electrical Engineer* of New York, Mr. F. W. Jones gives some particulars with regard to the use of leaks for the same purpose:—"The use of leaks was tried as early as 1870 upon the great overland circuits of the Western Union Telegraph Company extending between Chicago and San Francisco, a total distance of about £2,300 miles. The circuits were worked Morse and in sections of about 500 miles with automatic repeaters between them. Owing to the peculiarly dry nature of the vast prairies over which some portions of the circuits worked it was found that signalling was very tedious and required long and firm contacts of the sender's key to produce signals free enough from distortion by the excessive electrostatic effects to be received at either end of the line. For hundreds of miles the poles are standing in dry sand, and frequently the great expanse of sandy plain becomes highly electrified and clouds of the charged sand particles are driven by the high winds along or across the wires, which in turn become charged by contact with the electrified sand. These myriads of charges of high voltage unite into a dynamic current towards earth at each end of the particular circuit of the section invaded and on many occasions the entire suspension of business for the time is the result. This trouble is of greater frequency in very cold weather, and is then due to snowstorms instead of sand-storms. In 1883 I wrote Mr. W. B. Hibbard who had been superintendent of these circuits for several years, for information as to the value of the leaks, which consisted of high resistances placed at various convenient points along the lines to relieve the wires of their static charges. Mr. Hibbard's reply, dated Rochester, N.Y., August, 1883, is as follows:—'The high resistance leaks as a remedy for induction were tried in 1870, but proved worthless.' In some cases the resistances were strips of hard wood with a conducting line of carbon made by a lead pencil between two binding posts to which the line wire and earth were respectively connected."

Boiler Incrustations and Deposits.—At a meeting of the Junior Engineering Society, held on January 5th, an interesting lecture on "Boiler Incrustations and Deposits," was delivered by Prof. Vivian B. Lewes. The lecturer having pointed out the serious injury occasioned to boilers, and the waste of fuel due to the formation of incrustations, traced the history of various sources of water supply, and showed how the water acquired the power of forming deposits in steam generators. These deposits consist mainly of calcic carbonate, calcic sulphate, magnesic hydrate, and silica, the chemical processes which lead to their deposition in the feed-water differing in each case. Calcic carbonate, which constitutes the principal ingredient in fresh-water deposits, is thrown down in a dense form by the breaking up of soluble calcic bicarbonate under the influence of heat, and if it is nearly pure it forms a mud in the boiler, which can to a great extent be got rid of by blowing off. Calcic sulphate, however, is deposited by an entirely different action, as its solubility decreases with rise of temperature, high pressure, or great increase in the saline properties of the solution; and its wonderful power of hardening deposits and binding them together into an incrustation, which can only be removed by the use of hammer and chisel, makes it a most dangerous constituent of such deposit. This hardening power is due to the fact that it deposits from water in the form of small angular crystals, and in this form gets mixed with the calcic carbonate mud. As these crystals become heated, they lose water of crystallisation, and change their form into fine needle-shaped crystals, which bind the mass together. Magnesic hydrate, which is found in many scales, has always been supposed to be due to decomposition of magnesic chloride at a high temperature; but this is a mistake, the magnesic hydrate being produced by the interaction of magnesic chloride and calcic carbonate, which results in the formation of soluble calcic chloride, evolution of carbon dioxide and deposition of magnesic oxide, which, by combination with water, forms the hydrate. Examples were given of scales from various waters, and it was shown that fresh-water incrustations may be looked upon as consisting chiefly of impure calcic carbonate, whilst the deposit formed by the use of sea water is principally calcic sulphate. Brackish waters give incrustations consisting of nearly equal portions of these substances. The question of oily deposits on plates was next considered, and the lecturer pointed out that, according to recent researches, mere wiping of a boiler plate with a greasy rag causes a serious diminution in its power of transmitting heat, whilst with an oily deposit $\frac{1}{50}$th of an inch in thickness, plates in some cases became so overheated as to be unable to withstand the pressure upon them, and collapse of the furnace crowns sometimes ensued. The question of anti-incrustators was then dealt with, and the lecturer expressed his opinion that if manufacturers were obliged to use a hard water, the most reasonable method they could adopt was to soften it on a large scale before putting it into the boiler, as otherwise serious complications would arise in the boiler itself.

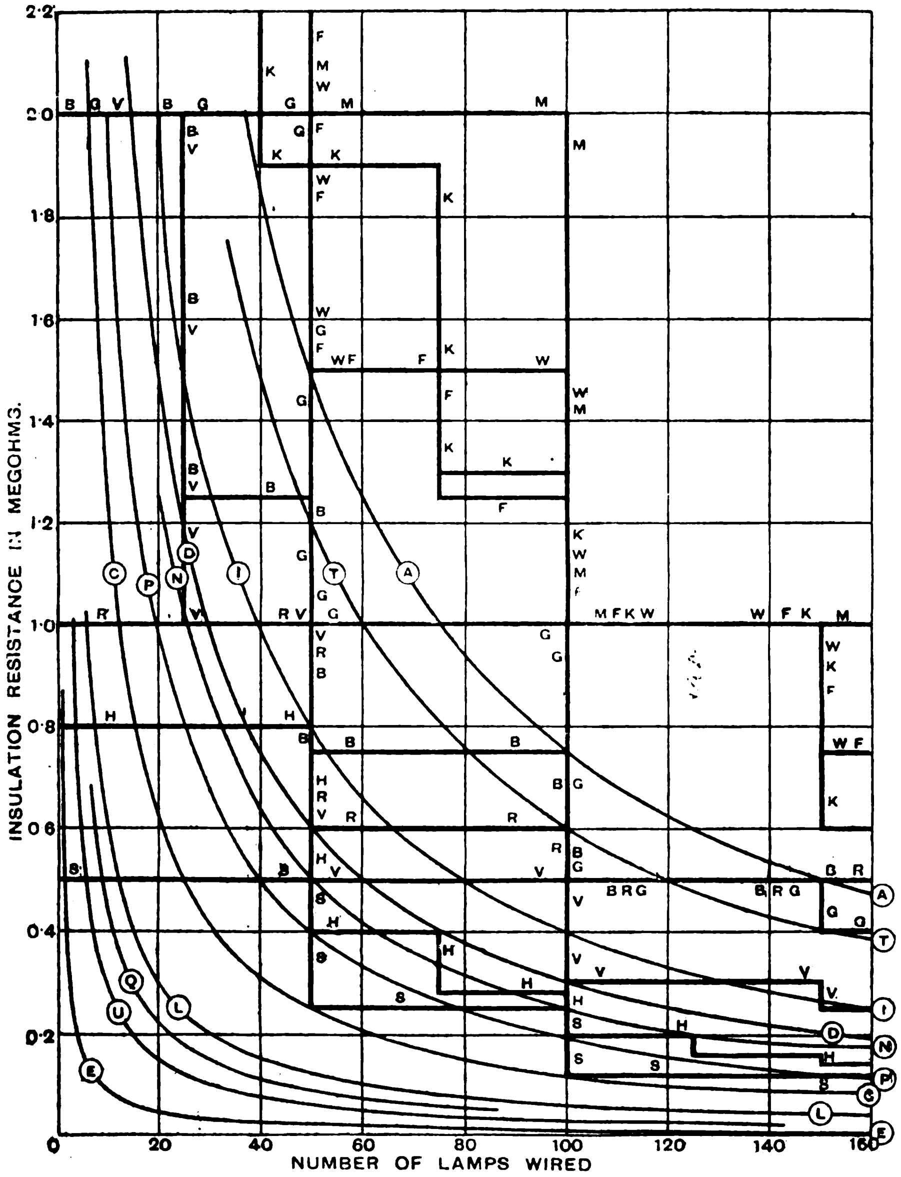
THE INSULATION RESISTANCE FOR HOUSE WIRING.

Since the publication in *The Electrician*, Vol. XXX., p. 657, of a set of curves showing the permissible variations of insulation resistance of house circuits on different systems of supply, a great many new rules have been formulated. Many of these have been published by supply companies not in existence at the time of our former article; while others are the result of the recent decisions of long-standing companies which formerly had arrived at no definite rules. Even at the present time, indeed, some of the provincial supply companies have not yet drawn up a set of rules on the subject, and are tentatively relying on the sagacity of the insurance companies. The result of a comparison of all the available insulation rules, reduced to one common standard of measurement, is given in the accompanying diagram of curves. The diagram which we published in April last gave only a few curves, and each could be clearly followed. But in attempting to make a complete collection it was evident that the diagram would be complicated, owing to their remarkable diversity as well as their occasional coincidence. The diagram thus fails to be a useful table of reference for wiring contractors, and serves rather as a symbol of the



Key to Diagram.

Index letter.	Company.	Nature of rule.
A.	City of London	75 megohms ÷ lamps.
B.	London Electric; House to House	Arbitrary insulation per lamp.
C.	Phœnix Fire Office; Liverpool Corporation; Lloyds	12·5 megohms ÷ lamps. (Doubled for alternating).
D.	Bradford Corporation	10 megohms ÷ amperes.
E.	Institution of Electrical Engineers	$\frac{1}{5000}$ part of current.
F.	Notting Hill	Arbitrary insulation per lamp.
	Kensington & Knightsbridge	do. minimum 5,000 ohms.
	Westminster	do. minimum 5,000 to earth; 75,000 wire to wire.
G.	Portsmouth Corporation	Arbitrary insulation per lamp.
H.	St. Pancras Vestry	do. minimum 5,000 ohms.
I.	Scarborough	40 megohms ÷ lamps.
K.	Chelsea	Arbitrary insulation per lamp.
L.	Leading insurance companies, including Guardian, Sun, North British, London, Liverpool and Globe, Alliance, London Assurance, Hand-in-Hand, Westminster, Royal Exchange, and others	$\frac{1}{20000}$ part of current.
M.	Charing Cross and Strand	Arbitrary insulation per lamp.
N.	Taunton Corporation	12·5 megohms ÷ 16-c.p. lamps.
P.	Brighton Corporation	20 megohms ÷ lamps.
Q.	London County Council (theatres)	$\frac{1}{15000}$ part of current; min., 5,000 megohms; max., 5 megohms.
R.	Manchester Corporation	Arbitrary insulation per lamp; min. 10,000 ohms.
S.	Whitehaven	Arbitrary insulation per lamp.
T.	Glasgow Corporation; Kelvinside	60 megohms ÷ lamps; min., 75,000 wire to wire.
U.	Chambre Syndicale des Industries Electriques	$\frac{1}{10000}$ part of current.
V.	St. James's, Pall Mall	Arbitrary insulation per lamp.
W.	Derby Corporation	Arbitrary insulation per lamp.

Digitized by Google

prevailing chaos and a convincing argument for co-operation and the adoption of a recognised system by supply companies and Corporations.

All existing rules more or less closely follow the logarithmic law—

$$R_i = \frac{k}{n}$$

Where R_i is the insulation resistance, n is the number of lamps wired, and k is a constant about which the diversity of opinion arises. Some of the rules follow this law absolutely, giving the rectangular hyperbolæ A, I, L, U, &c., in the set of curves; others give stepped rectilinear curves which oscillate about a mean hyperbola. The choice of a constant, k, ranges from 130 down to 0·6 megohms per lamp, this latter being the rule of the Institution of Electrical Engineers. Up to date, however, no supply company or Corporation has been discovered which has put practical faith in this feeble curve, E, which clings so pathetically to its asymptotes; and the majority require a standard of insulation from twenty to one hundred times greater.

It should be observed that while the requirements of the Institution of Electrical Engineers are amply sufficient from the point of view of mere insulation to prevent danger from fire, or any serious leakage, experience has shown that a house circuit giving such a low insulation resistance cannot be sound. The rubber covering of the wires and cables is sure to be mechanically bad, liable to crack or perish, if the insulation resistance measured as a cable is less than 300 megohms per mile. This, however, hardly enters into the resultant insulation of the complete work, which depends on the quality and condition of the switches, ceiling roses, fuse boards, &c., and it is generally acknowledged that an insulation of only 6,000 ohms, that is, $\frac{1}{120}$th of a megohm, is far too low for 100 lamps.

The rules represented by the hyperbolic curves extend indefinitely in either direction, with the exception of that of the regulations for theatres of the London County Council, which very sensibly stops at a minimum of 5,000 ohms, and a maximum of 5 megohms. The hyperbolic curves in the diagram are in some cases stopped off for the sake of clearness. The stepped curves all run out indefinitely to the right hand of the diagram, but in some cases a minimum insulation is given, considerably lower than that demanded at the first test. The upper limits of some of the curves are not included in the diagram. The companies, represented by the stepped line F, viz., the Kensington and Knightsbridge, Notting Hill, and Westminster demand 2·5 megohms for 25 lamps, and 5 megohms for 12 lamps. The House to House Company and the Charing Cross and Strand Company ask for 5 megohms for 10 lamps; while the Chelsea Company expect 2·4 megohms for 40 lamps, 3·1 for 30, 4·6 for 20, and appear to be satisfied with nothing less than 8·4 megohms for 10 lamps.

For 60 lights, a good average number, the various authorities stand in the following order, and demand the following insulations:—

	Megohms.		Megohms.
Charing Cross & Strand	2	St. James & Pall Mall } Bradford .... }	0·5
Chelsea	1·9	Taunton	0·416
Notting Hill } Kensington and Knightsbridge } Westminster } Derby }	1·5	St. Pancras	0·4
		Brighton	0·33
		Whitehaven	0·25
City of London	1·25	Phœnix } Liverpool } Lloyd's }	0·21
Portsmouth } Glasgow } Kelvinside }	1		Ohms.
		Leading insurance Co.'s	100,000
London } House to House }	0·75	London County Council	70,000
		Chambre Syndicale ...	50,000
Scarborough..	0·66	Institution of Electrical Engineers	25,000
Manchester	0·6		

In the stepped curves there is exhibited considerable diversity of opinion as to the range in the number of lamps over which it is considered advisable to allow the same insulation resistance. In curve H of the St. Pancras Vestry the range is everywhere moderate, so that the quality of the work need not be affected by any consideration of the number of lamps to be wired. But in curve M of the Charing Cross and Strand Company the ranges are very large indeed, and as it is possible for a consumer with 50 lamps to get off with precisely the same insulation as the consumer with 99 lamps, there is a tendency to pass inferior workmanship and materials in the former case. Narrower limits of range of constant insulation resistance are to be recommended in the majority of these stepped curves, making the steps more numerous and less deep.

Many of the stepped curves overlap completely within th limits of the diagram, in which cases the curves are lettered wit the several index letters of the supply companies referred to a the foot of the diagram. Many, too, overlap during only a par of their length, in which cases the overlapping parts ar lettered with the index letters of the supply companies whos rules thus partially coincide. By following the course of an one index letter, the path of the corresponding curve may easil be obtained. The simple hyperbolæ are marked by letters er closed in circles, to distinguish them from the plain letter marking the stepped curves.

The majority of authorities specify the insulation accord ing to the number of lamps; one or two specify 16-c.p. lamp and a few take amperes instead of lamps. The curves ar drawn on the basis of 8-c.p. lamps, taking three to an amper and at 100 volts. The size of the lamp does not appear to u to have much to do with the insulation of the wiring. Ther seems to be no reason why a branch, with its fuse and switc for a 100-c.p. Sunbeam lamp, should have an insulation resis ance some twelve times greater than a branch carrying a 8-c.p. lamp.

One company, and one only, so far as we know, has nc deemed it advisable to adhere to any fixed scale, but prefers t leave it to the judgment of its wiring inspectors. This the Metropolitan Company, who, we understand, have exper enced no trouble in the matter; the wiring contractors hav been ready to acknowledge defects where these have been di covered, and only in rare cases has an appeal been made t insurance companies or to the owner of the property, and th with immediate and satisfactory result.

While the great diversity of the rules revealed by glance at our diagram calls loudly for some mean to whic wiring contractors can accustom themselves, the experience o so wide spreading a company as the Metropolitan compels us t consider the wisdom of binding all concerned to certain figure which even if they are the expression of a logarithmic formula are purely arbitrary. The insulation resistance of a house ci cuit, after all, has, as we have observed, little if anything to d with the quality of the cable, but is a measure of the moistur on the surface of cut-outs, lampholders, switches, and wall The effect of weather is familiar to every wiring contractor, an when the inspector is allowed no discretion for atmospheri conditions or for the length of time during which the wirin and fittings have remained unused in an unoccupied hous injustice may be done to good work, and a conscientious co tractor may suffer. We have known a very poor insulatio brought up to the mark by leaving a testing battery, givin over 100 volts, on the wires all night, before the inspector' test; and we have known switchboards to have been toaste with coke fires, a most dangerous proceeding, for the same pu pose. In cases of damp due to fogs or rain and not to ne plaster, the supply company might allow connection to b made, putting a lamp in series with each main, for a few hour before a final test.

AN ENGINE BUILDING RECORD FOR 1893.

The records of the year's work which we receive from many electrical firms consist to a great extent of accumulations of small work, and they are almost invariably confined to the manufactures and work of these particular firms; nor is it possible, even by selecting the larger items thus furnished, to obtain a record of the work of the year. Some information which we have received from Messrs. Willans and Robinson is, however, of a different character. Manufacturing no dynamos or other electrical plant themselves, a larger number of dynamos pass through their hands than is the case with any other engine builders in this country. The singularly close connection between the Thames Ditton Works and the dynamo-making industry is accounted for by the direct driving and consequent mounting of dynamos on the same bed with the engines.

Digitized by Google

Many other engine makers rarely see the dynamos which are to be driven by their engines, and do not come into contact with the dynamo builders. We make no comparison between the business done by this firm and by other engine makers; the columns of the tables issued with our last number are sufficient to show the popularity of Messrs. Willans and Robinson's work, and their order book undoubtedly serves in large part as an index to the year's central station work.

The apparent ignorance which exists about the position attained by the Willans engine on the part of those who might be expected to know all about it is rather curious. Only last week our contemporary, the *Engineer*, lamented that up to the present no engine builder has produced an engine "capable of running with absolute steadiness with variable loads for a period of about 14 hours, during which it cannot be stopped for an instant. . . . It is not enough that the engine shall comply with the conditions for six months or a year; it must *always* do so." It might be thought that in this connection the Willans engine would be at least alluded to, but it is not, and, indeed, the references to modes of failure seem to show that the writer has open or double-acting engines only in view. The *Engineer* is even "certain that there is not one engineer in charge of a central station of any importance who will not fully endorse what we have said," and our contemporary then chides the station engineers, who "either lack the ability or the confidence to dictate to the mechanical engineer or engine builder, and take very much what the latter place before them." Now there is no doubt that station engineers have still plenty of difficulties to contend with, but we should like to hear whether engineers such as Prof. Kennedy, who has the responsibility for great stations like those of the Westminster Company, or that at Glasgow; Mr. Preece, with his years of experience with what are nothing less than large central stations for Post Office service, and his more recent experience at Bristol; Mr. Shoolbred, in respect of the large installations at Bradford and at Brighton; Prof. Henry Robinson, who can speak for such stations as St. Pancras and Norwich; Messrs. Holmes and Vaudrey, with their great experience of central-station engines at Liverpool and at Birmingham; Mr. Sydney Dobson, of the St. James's and Pall Mall Company; or the engineers of the Kensington and Knightsbridge or of the Chelsea Companies—would agree that the running of their engines ever enters into their heads as a subject of serious difficulty. In all the cases named the English single-acting engine, *i.e.*, the Willans engine, is used; the troubles and doubts which the *Engineer* gives voice to come from America or from the Continent, where they have only lately broken loose from the—in England—well-nigh obsolete plan of belt or rope driving, and where they are unacquainted with a really good single-acting engine for direct coupling, and have consequently been driven to the costly and unsatisfactory plan of making huge slow-running dynamos merely for the sake of coupling them to slow-running engines.

The works at Thames Ditton are almost wholly devoted to the making of engines for electric lighting, so much so that new works are about to be erected for the making of engines for other purposes, chiefly large engines for driving cotton and flax mills. The first point of interest, then, for the electrical engineer, is found in the rapid development shown by the following figures:—

		H.P.
Engines ordered in	1891	11,100
„ „	1892	14,300
„ „	1893	18,950

These speak well for the electrical industry in times of deep depression. It will be remembered that the firm makes very few small engines—*i.e.*, small in the sense of horse-power. There are few below 80 H.P.; in fact, the average size for the year 1893 is about 128 I.H.P.

The year's work includes the erecting and starting of engines, ordered previously, in the following stations:—

	H.P.		H.P.
Bristol	1,440	Dundee	660
Glasgow	1,210	Norwich	300
„ (Kelvinside)	270	Naples	400
City Lighting Company, Bankside Station	1,440	Hobart Tramways, Tasmania	600
Carnaby Street, London	1,060	Knightsbridge	360
		Whitehaven	240

to which a private station of the North Western Railway, at Crewe, deserves to be added, with 384 H.P.; and the very notable installation at the Small Arms Factory at Herstal, in Belgium, where a 300-H.P. Willans engine was supplied, in addition to a Corliss 500-H.P. engine, to generate current for the motors by which the whole of the shafting and machines are driven. The Corliss engine came from the famous shops of Messrs. Vanden Kerchove, of Ghent, and it is noticeable that this is one of the two firms who have since become licensees for the manufacture of the Willans engine on the Continent. The engines above enumerated amount to nearly 8,700 H.P., irrespective of a great many smaller orders carried forward from the preceding year.

The principal central-station orders received during 1893 were from, or on account of, the following:—

	H.P.		H.P.
Liverpool Company	1,920	Chelsea Company	200
Westminster Company	1,160	Nottingham Corporation	650
Brighton Corporation	720	Aberdeen Corporation	320
Birmingham Company	200	Lancaster Corporation	400
St. James's and Pall Mall Co.	550	Hampstead Vestry	860
Bradford Corporation	400	Warrington Corporation	270
St. Pancras Vestry	400	Dewsbury Corporation	400
Bristol Corporation	720	Nelson Corporation	135
Glasgow Corporation	720		

The following private stations deserve enumeration:—

	H.P.		H.P.
General Post Office	400	Royal Albert Docks	600
Lancashire and Yorkshire Railway (Victoria Station, Manchester)	300	Southampton Docks	240
		Birmingham Grand Hotel	180
		Holborn Restaurant	400

Not much has been done yet for Continental lighting stations, but the following may be named:—

	H.P.		H.P.
Rotterdam	400	Caen	270
Biarritz	180	Naples (already mentioned)	400

The above figures account for nearly 13,000 H.P. out of the (approximately) 19,000 H.P. ordered during 1893. The remainder is for minor installations, and for miscellaneous work other than electrical. Of the 13,000 H.P., over 7,000 H.P. is in the form of repeat orders from those who are already users of the Willans engine.

It will probably be agreed that there is more satisfaction in the foregoing figures, furnished by one firm of engine builders, than in the aggregated returns of many electricians, and it is additionally satisfactory to be able to add that the prospect of orders for the Spring is said to be excellent, and to promise at least as much increase over the figures of 1893 as that year showed over 1892.

Messrs. Willans and Robinson are amongst the few English engine makers who exhibited at Chicago. They put down two condensing engines, one of 360 and the other of 135 I.H.P., to drive two of the lines of shafting in the British section; the third line was driven by a horizontal engine, of about the same power as the largest Willans engine. Owing to an accident the Willans engines, for about two months, had to drive the whole of the shafting in the British section and a part of the German section, and it was officially reported that there had never, from the time of starting, been a break-down or a stoppage of either engine. It was said that this statement could scarcely be made of any other engine in the exhibition, owing, we understand, to the great quantity of water which passed through the steam pipes, and which led to many breakdowns; the Willans engines, from their position, were singularly exposed to this danger, but they escaped entirely. By permission of Messrs. Siemens Bros. and Co., Messrs. Willans and Robinson also exhibited a combined plant consisting of a fine Siemens dynamo and compound Willans engine of 300 I.H.P., being one of the sets belonging to Messrs. Siemens' own station at Woolwich. This plant was in constant use, and attracted great attention; it is unfortunate that it was not possible to compare it with American plants of similar size. We feel no doubt that, both as regards efficiency and economy, it would have given results very surprising to American engineers.

THE CHANGES PRODUCED IN IRON BY ITS PERMANENT DEFORMATION WHEN COLD.

According to leading authorities iron exists in two allotropic states, which have been called by Osmond α-iron, or soft iron, and β-iron, or hard iron, and some recent experiments of M. Georges Charpy, recently published in the *Comptes Rendus*, tend to corroborate this theory. M. Charpy experimented upon more than 300 bars of different kinds of iron, differently tempered, annealed, or hammered. To all these samples M. Charpy applied tensile stresses by means of Col. Maillard's machine, the elongations produced being automatically registered, and he invariably obtained one or other of the two

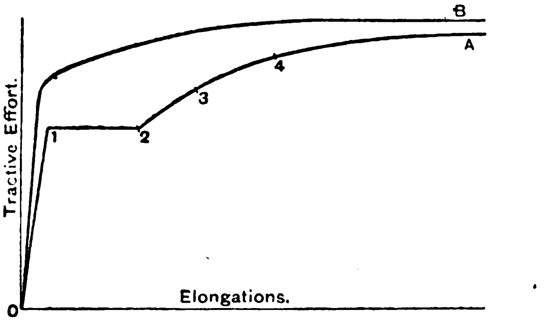

FIG. 1.

curves shown in Fig. 1. Curve A, with its well-marked step, was always obtained with, and only with, annealed iron or steel. Curve B was given by hammered or tempered steel and iron, and by other metals. The remarkable elongation which takes place in the case of the brands giving curve A leads one to suppose that it corresponds to a change in the state of metal itself, and therefore in all its properties. M. Charpy, therefore, experimented with a view to discover whether the residual magnetism curve also showed a step. Bars were submitted to tensile stresses, and at the points 1, 2, 3, and 4 the bars were taken out and magnetised, the residual magnetism being measured 24 hours afterwards by means of a ballistic

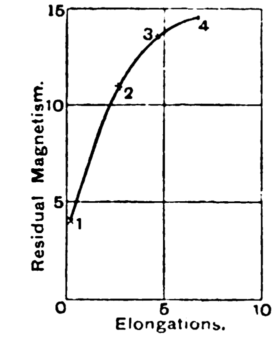

FIG. 2.

galvanometer. The following are some of the results obtained, the residual magnetism curve of series II. being shown by us in Fig. 2.

Numbers.	Tractive effort. Kg. mm^{2}.*	Permanent elongations. mm. per 10cm.	Residual magnetism (scale divisions).	Residual magnetism after annealing.
	Series I.—Soft Iron.			
1	25·20	0·0	2·5	1·0
2	25·20	1·6	4·8	1·5
3	31·10	4·3	6·5	1·2
4	33·60	6·0	6·5	1·5
	Series II.—Extra Soft Steel, 0·12 per cent. Carbon.			
1	34·2	0·2	4·0	3·5
2	34·3	2·7	11·0	3·5
3	35·5	4·7	13·5	3·5
4	41·1	6·8	14·5	3·5
	Series III.—Medium Hard Steel, 0·5 per cent. Carbon.			
1	35·5	0·0	8·0	3·5
2	38·5	1·3	14·5	4·0
3	41·0	2·9	17·0	4·0
4	52·5	4·6	17·0	3·5

* 1 kilogram per sq. mm. = 0·6 ton per sq. in.

The last column gives the results obtained by reheating pieces of the same bars up to 800°C. and remagnetising them; this latter experiment being carried out with samples taken from the bars, the absolute values obtained are not, of course, comparable. It was ascertained, moreover, that the metal, when submitted to tensile stress after annealing, again gave a stepped curve. It was possible, therefore, by a successive stretching and annealing, to make the step disappear and reappear five times in the same bar. It will be seen by Fig. 2 that the residual magnetism increases greatly during the straight part of curve A, Fig. 1.

THE PARIS CENTRAL TELEPHONE EXCHANGE.

At the present moment Paris is served, and by all accounts not very satisfactorily, by 12 telephone exchanges. The number, however, is to be ultimately reduced to four, viz., (i.) Rue Gutenberg, 6,000 subscribers; (ii.) Avenue de Wagram, 3,000 subscribers; (iii.) Rue de Belleville, 6,000 subscribers; (iv.) an exchange to be erected on the left bank of the Seine. In some articles appearing in *L'Electricien* in December last, M. Em. Dieudonné describes in great detail the large new exchange which has just been completed in the Rue Gutenberg, an exterior view of which is given in Fig. 1. The building consists of a basement, ground floor, and four stories, on each of which there is a spacious hall 215ft. long by 33ft. broad. The first floor is devoted to the apparatus connected with the inter-urban wires and the auxiliary exchange wires. The second floor is taken up by a 6,000-subscriber multiple switchboard. The third and fourth stories are still unoccupied. The building is lighted throughout by arcs and incandescents supplied with current from the municipal station at the Halles, the lighting of the operating hall being supplemented by sunlights. The entire building is ventilated and warmed on the Anthony system. In the basement a fan sucks in a supply of air from outside, which is passed over hot-water pipes to a humidifier composed of a series of rotating iron discs arranged close together on a common axle, the lower portions of the discs dipping into water. This warm, moist, purified air is then distributed under pressure to all parts of the establishment, which requires on an average over one million cubic feet of air per hour. As will be seen by the view given in Fig. 1, the front of the building contains a considerable amount of glass; to mitigate the cooling influence of this expanse of glass in wintertime a special hot-air pipe is run along each gallery close to the glass, which is thus constantly swept by a stream of warm air.

The telephone cables employed in Paris are of three kinds, viz., 100-conductor lead-covered cables, 14-conductor lead-covered cables, and Fortin-Herrmann cables, *i.e.*, cables insulated by prepared wood beads, and enclosed in a lead tube. The cables terminate in succession at hermetically-sealed boxes, called "terminal boxes." These boxes (Fig. 2) have on their faces two horizontal rows of insulated terminals, which project into the interior. To the inside ends are connected the conductors coming from the outside cables; to the outside ends are connected the wires running to the "distributor."

The terminal-boxes are not only used inside the exchange, but outside at certain points in the subways, where they play an important part in keeping up the insulation of the lines. A small pipe will be observed coming out at one end of the box (Fig. 2); into this a pipe forming part of a compressed-air system is fitted. The compressed air is taken from the Popp mains, and after having been passed through a series of boxes filled with pumice-stone or some other desiccating material it is forced into the terminal-boxes.

From the terminal-boxes the wires run to the distributor, where all the necessary rearrangements of the circuits are effected. The distributor, which is not at all unlike a wine-bin in appearance, consists of vertical and horizontal metallic pillars, terminal boards, such as the one shown in Fig. 3, being attached to them. The cables coming from the terminal-boxes pass to the terminal boards of the distributor, and thence onwards to the switchboard upstairs.

In many countries the subscribers are given magnetos to call up the exchange with; in Paris Tudor accumulators are used for that purpose. The exchange microphones are worked by block-cells, and the subscribers' by Leclanché cells.

The multiple switchboard was invented in 1880 by Messrs. Haskins and Wilson, of Chicago. How telephone exchange work was carried on before the introduction of this great improvement is graphically detailed by M. Dieudonné:—(1) The subscriber first of all rang up the exchange, and awaited the answering ring. He then gave his order and hung up his receiver. (2) The exchange operator then rang up the member asked for, and afterwards the asking member. (3) After having joined the two subscribers, the exchange operator listened to hear if conversation was commenced. (4) On the termination signal being made, the exchange operator again listened to make sure that the conversation really was over. But this was not all. All the wires running into the exchange did not terminate at one and the same

Digitized by Google

board, sufficiently small to allow the exchange operator, without appreciable effort to connect any two subscribers together. Sometimes the annunciators of two subscribers were a long distance apart, and to connect them together consequently required long

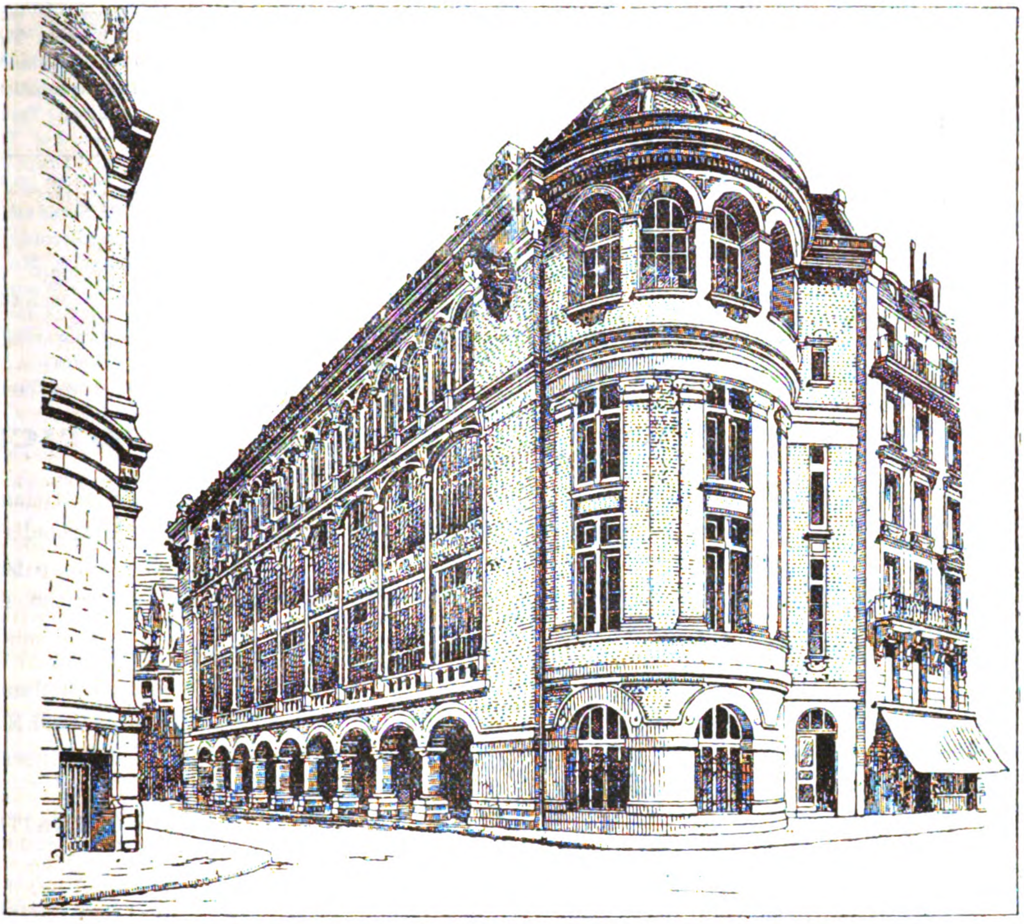

FIG. 1.—The Paris Telephone Exchange.

lengths of flexible. Subscribers attached to two different exchanges can only be joined up by means of inter-exchange wires. These inter-exchange wires ran to a special board at each exchange, the

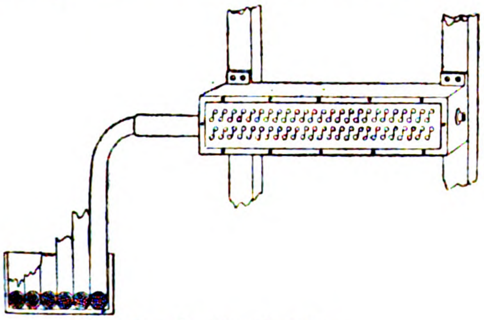

FIG. 2.—Terminal Box.

wires of the exchange subscribers being also brought to a subsidiary board. The result was that at busy times there was such a profusion of flexibles, and such a tangled network of wires, that circuits were frequently unintentionally broken, giving rise to lively

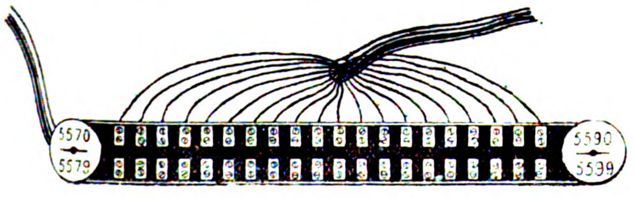

FIG. 3.—Terminal Board.

complaints. Whoever, remarks M. Dieudonné, has witnessed the spectacle, retains an indelible recollection of it; there was such a tumult of discordant noises that one almost thought one was in an aviary!

The introduction of the multiple switchboard has, however, brought peace to the land of telephony; not only has it enabled us to greatly reduce the number of our exchanges, in the majority of cases one single exchange sufficing, but it has made the connecting together of subscribers both simple and rapid. The principle of the multiple switchboard is merely to divide up the switchboard into panels of dimensions sufficiently small to enable the exchange operator to work it by means of the usual plugs and flexibles, and sufficiently large to accommodate the spring-jack terminal of *every* subscriber to the exchange. A subscriber's wire thus runs in succession to its appropriate terminal on *every* panel of the entire board, and finally to the panel containing the annunciator. Each exchange operator has, therefore, within reach the spring-jack terminals of *all* the exchange subscribers, a certain number of whom have their annunciators worked at each panel, and the operator can, therefore, without further ado, and without moving from her seat, connect up any two exchange subscribers.

The multiple switchboard in the Rue Gutenberg consists of 23 sections, 240 subscribers being allotted to each operator; there are also two sections devoted to inter-urban lines, 10 sections devoted to inter-exchange lines, and three sections devoted to suburban exchanges. The connecting-up of all these sections necessitated more than one million soldered joints.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

SATURDAY, January 13th.

ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING.

11 a.m. General Meeting at University College, Gower-street.

2 p.m. Afternoon Meeting, when Papers will be read.

TUESDAY, January 16th.

SPECIAL NOTICES.

We shall shortly issue with "The Electrician" a COLOURED MAP, showing the Streets in the Metropolis in which Mains for Private Lighting are actually laid, up to January, 1894, together with the areas allotted to the different Supply Companies.

In an early issue will be published a fine STEEL-PLATE PORTRAIT of Mr. ALEXANDER SIEMENS, President for 1894 of the Institution of Electrical Engineers.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; and Joseph Wilson Swan, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

TELEGRAPH STATISTICS.

Although the electric telegraph has been in existence now for half a century, and has attained to amazing proportions, the statistics of its growth are singularly meagre, and, perhaps, even more singularly complicated; not that the materials are wanting either in authenticity or detail, but they vary so much in method of collection, in data upon which the figures are based, and in diversity of usage in different countries, that any general or instructive comparisons are, as yet, beyond our reach. Such, at all events, is the case as regards overland telegraphy. With the cable lines the information, if supplied, would be of a simple and more uniform kind, one reason for which is the proprietorship being largely in the hands of one nationality and the working more nearly identical. But on land each country has not only peculiarities of its own in respect of apparatus, but also of valuing its telegrams, apportioning its receipts, and assigning its expenses. Add to this the circumstance that in some countries—notably France and Germany—the revenue, as well as the staffs, have been mixed up with those of the postal service, and it will be seen that financial comparisons can be matters only of estimate and conjecture. For the smaller matters of percentages, per head and per mile, the

Digitized by Google

professional statistician will be able, as usual, to prove anything he pleases, according as he does or does not allow for the fulness of the land or the emptiness of the heads which he is counting up.

For what it may be worth, however, and as an instalment of something better to come, we lay before our readers this week a table of telegraph statistics which has at least the merit of novelty. It is compiled chiefly from the Official *Journal Télégraphique* of Berne, and, with due allowance for the explanatory and qualifying notes accompanying the table, may be accepted as the most trustworthy account of the facts hitherto obtainable. Without these notes the respective items would sometimes appear unaccountably conflicting. For example, the disproportionate staff of Great Britain and Ireland includes nearly 60,000 persons described as temporary *employés*, a description which can only apply to unattached agents of the service, who can only be fairly included on the supposition that the corresponding agents in other countries are also counted in—which seems unlikely. Again, as regards appliances, the telephone is in some cases included under the head of "other systems," but excluded elsewhere. The wires and instruments—possibly the offices as well—pertaining to the railways are not reckoned in some of the countries, notably the British railways, which own a tremendous property of that kind; whilst in other countries where the State owns the railways, wholly or partially, the railway telegraphs appear to be embraced in the total. The same observation applies to the telephone system, whose independence or nationalisation is still far from being uniform throughout Europe. Some clue to the closeness of the connection between the Telegraphs and other State departments, including railways, is furnished by the number of service messages, which in France reaches a prodigious total, Germany being a bad second. It is to be regretted that no figures under this head are furnished for the British telegraph; if railway messages which are sent free were treated on the same principle they would be counted as "service," and together with other departmental telegrams, including postal, would make up a total that would run that of France rather close.

Searching for details of a more practical kind, we should be inclined to single out the figures relating, first, to the "length of conductors"; second, the number of "instruments"; and lastly, the "number of telegrams." Length of line signifies very little except as indication of extent of territory covered. As a rule the conductors average three times the length of line; and we note in passing that this average has been attained even in British India, a striking testimony to its commercial development, although, of course, the number of offices, judged by population or mileage area is significantly small. In Belgium, however, a compact little country, the conductors are nearly five times the length of lines, and in Holland about four times. In the British Isles the proportion is still greater, the available wires being more than six times the length of the geographical mileage; and to this we may add a still greater carrying capacity due to the larger use made of fast speed and multiplex instruments. As regards instruments, a criterion which we take to be of more importance than the number of offices, Germany, with its population of forty-nine and a-half millions, is the only country that approaches Great Britain and Ireland, with a population fewer by ten millions. But when we examine the systems, it is found that the Morse is three times more numerous in Germany, whilst its "other systems" are almost entirely represented by telephones, whereas those of Great Britain are represented by instruments as rapid as the Continental type of Morse, and include some 600 of the fastest instruments that science or ingenuity has yet devised. It is interesting to note, however, that these high-class appliances are gaining favour on the Continent, and present quite a respectable figure in such countries even as Italy and Norway.

The gross totals of telegrams dealt with by the respective countries would furnish material for a small volume of annotations and inferences if all the varying conditions and circumstances of the several countries could be fairly taken into account and justly estimated. But the result, after all, might not be particularly edifying. For the present the facts alone concern us; the inferences may be left to those who are in need of them. How hazardous they may be on the one hand, and how attractive on the other, is shown by the column of averages under "General Information." Victoria, it seems, sends nearly twice as many telegrams per head as any European country. A good deal depends, as we said before, on the heads. They must be few in number in Victoria, and of superior quality. A more substantial fact set forth in the Table, and not resting on any averages, is, that inland telegrams number in this country about twice as many as in France, and three times as many as in Germany. Our foreign telegrams—excluding, however, those dealt with entirely by the submarine cable companies—are outnumbered by those of Germany, but exceed those of France. The same observations would seem to extend to the financial side of the account; but here so many considerations remain clouded under the official veil that we hesitate to make comparisons, much less draw conclusions. British Indian telegraphs appear to be paying their way handsomely, owing, doubtless, largely to its great transmitted traffic between west and east, and Australasia. Of European countries Switzerland seems to be the only one that is counting its telegraph as a paying concern. Possibly the same may be said of Sweden, though not of Norway. In conclusion, we have only to remark that while we are thankful for the information placed at our disposal by the Bureau International something more is expected. Particulars as regard some other countries are still wanting; and above all, the figures supplied ought to be based on one uniform method applicable to them all, and should plainly distinguish between State telegraphs as such, and telegraphs which are not of the State.

THE NEWPORT TENDERS.

Copies of the specification for the Newport municipal electric lighting plant, and a report on the tenders, have been handed to us by Mr. R. Hammond. The specification does not call for any special remarks. It relates to the complete plant for an alternate current station, with continuous-current arc lighting. Few details are given, and no promise of the surprise that was to follow in the report. The second page of this curious document contains the following passage:—"The specification throughout was drawn by me in such a manner that, though the quality and capacity of each piece of apparatus was clearly defined, there was no limitation as to type, so that no manufacturer of high-class apparatus was excluded from tendering." The obvious interpretation of this is, that had Mr. Hammond attempted to go into details, he would have described a class of plant which no manufacturer of high-class apparatus would care to touch. But perhaps he did not mean this. He then proceeds to explain the rules of an interesting game which he calls an appraisement, or system of adjusted prices.

The whole of the rules are unfortunately not given, much being left to imagination. Where a contractor has misunderstood a specification, or where deviations are made subsequent

Digitized by Google

to its issue, adjustments of price, not of an artificial but of an actual character, are not unusual. An artificial system is carried out here through nearly every section. The method reminds us of the old method of rating and time-allowances of yachts. The length (minus three-fifths of the breadth) was multiplied by the breadth, and again by half the breadth, the product was divided by 94, and this gave the tonnage. Much more arithmetic followed, which we need not describe, but nothing was left to judgment; for the practice of making allowances for the skill of the captain and the income of the owner was never definitely adopted. Instead of simply recommending one tender in each class, with or without reasons, one tender is selected, generally without any given reason, as a standard, and then, by a succession of purely arbitrary credits and penalties, odd sums are added to or knocked off from the other tenders, until an entirely new set of prices are arrived at. These prices are not to be paid to anybody, they are only part of the game.

In the first section on boilers, the Davey-Paxman Economic is selected for the doubtful honour of acting as a standard. The first move of this pastime is to credit all Lancashire boilers with £37. 10s. "for superior accessibility and permanence as compared with" the unhappy standard. Mr. Hammond thinks that two of them have "better evaporative surface," and credits them with £15 each, and so on. The standard appears to be blamed for having long tubes, and "suffers," at least so Mr. Hammond thinks, from the position and arrangement of its tubes, and access for cleaning, &c. "Freedom from priming," as judged from the tenders by Mr. Hammond, is reckoned as worth £100 in several cases, and "means of access" as £60. Messrs. Fowler and Co., of Leeds, do not get a place in the first handicap.

The engine section reveals the full fun of Mr. Hammond's manipulation. A casual glance at these pages at first suggests that they have something to do with mechanical engineering, but closer examination only reveals more of these arbitrary and rather childish "adjustments." Bearing surface is penalised or credited at £1 per square inch, volume swept out by pistons per minute at 5s. per 1,000 cubic inches, and mechanical efficiency at £2 per annum for 1 per cent., or £30 capitalised, and so on. After all adjustments in this section, Messrs. Fowler and Co., of Leeds, come out worst, being nearly £850 higher than the lowest tender. By an odd trick of this game the standard engine, after all this nonsense, is finally recommended, as a set off, perhaps, to the boiler section, for it is that of Davey Paxman.

Section D on dynamos ought to have been interesting, but the author was wearying of the thing, and gives no details. If a bonus and penalty system had been candidly stated in the specification, as was done by Dr. J. Hopkinson for Manchester, to be decided, not by the mere off-hand assertion of Mr. Hammond, but by actual test, there would be some reason in the idea. When a consulting engineer attempts to do something more than give advice, to select, and to recommend tenders, and begins to teach manufacturers their business, or, as in the case of Prof. Forbes, to take it out of their hands and to do it for them, he is likely to attract criticism, and his critics will be men who have spent their lives in practical work in different departments. Adjustments such as those pretended in the Newport report would not be without interest if they were based upon experimental data, but to make them on sundry items in the tenders, when no hint of such adjustments was given in the specification is simply throwing dust in the eyes of the Newport Corporation. The specification having invited all kinds of alternators, and containing nothing whereby any "manufacturer of high-class apparatus was excluded," the report proceeds to disparage all alternators with revolving fields, and this is the reason. "As regards the point of mechanical strength, it is obvious that the class of machines in which the armature rotates can, on account of the lightness of their moving parts, safely be made much lighter and more cheaply than those in which the magnets form the rotating part. For the same reason they can be run at a higher speed with equal safety." So Mr. Hammond seems to like a light, cheap, fast-running machine! We are almost compelled to reconsider our views about that sentence on the second page. To support this choice, which was not hinted at in the specification, lists of towns using the two kinds of alternators are given. No figures of merit are appended to these towns. Brighton is one; one of Mr. Hammond's pioneer stations. It might have been marked "goodwill, £5,000; plant *nil*." Whether the adjustments in this section take account of the colour of the paint or the weight of the oil cups we do not know. Messrs. Fowler and Co. come in first this time. Tenders for continuous-current arc lighters were invited, and for lamps to suit the arc lighters. Two pages are devoted to discussion of Messrs. Ferranti and Co.'s rectifying apparatus, and at the end, *apropos* of nothing in particular, it is announced that Messrs. Fowler and Co. have won again. This firm's tender for a switchboard is more than twice that of Messrs. Crompton and Co., who, however, are not in the running; perhaps there were no ornamental corners on their tracing. Siemens and Co. are close to Fowlers; "between these two boards, however, I must leave the Committee to judge, as I am naturally somewhat prejudiced in favour of the switchboard of which I have had such satisfactory experience over so many years." This is admirable candour, but why deal with the switchboard alone in this manner? Why not apply the same briefly and in a straightforward manner to the whole job? The section on arc lamps finds Crompton and Co. lowest after the "adjustment" business has been done, but the specification is thrown over, for "the first step, however, is to write to each tenderer asking him the cost, if any, of the substitution of an alternating-current lamp for a continuous-current lamp." Messrs. Crompton and Co. are recommended for culverts, but not without some sneers about the field being new to them, and the information that the pattern of one of the iron boxes "is one which I had a hand in designing some years ago."

After all this tedious business a general summary is given, not of the lowest, or "adjusted," or recommended tenders, but of "the prices at which good apparatus can be obtained under each section." The total comes to £22,564. The totals of the four firms who tender for all sections stand thus:—

Fowler	£24,480
Brush	24,203
Siemens	23,886
Crompton	20,789

The game is not over. There is one move more. It is all on the last page. "It is interesting to compare this figure with the price at which four of the tenderers have expressed their willingness to undertake the whole contract, viz.:—

Brush	£24,203
Siemens	23,500
Fowler	23,384
Crompton	20,780
Average	£22,966"

With a rather unpleasant remark, Messrs. Crompton and Co. are bowled out, and the rest of this extraordinary report

Digitized by Google

considers "the policy of giving out the whole of the contract to one firm," and "the many advantages accruing to this plan." The result of the whole thing is that at a special meeting of the Corporation on Tuesday last the Electric Lighting Committee recommended that the tender of Messrs. JOHN FOWLER and Co. be accepted, but it was decided by 21 to 11 votes to refer the matter back, and to hear Messrs. CROMPTON and Co. as to the details of their tender. If the report had consisted of the last page alone, Mr. HAMMOND would have had an excellent reason for recommending Messrs. FOWLER and Co., on the grounds given in the switchboard section, to which we have alluded.

OBITUARY.

HEINRICH HERTZ.

Not a student of physical science on the planet but will realise and lament the sad loss conveyed by the message, "Hertz is dead." After thirty years of study and preparation, he achieved his great discovery in the comparative quiet and isolation of Karlsruhe, and now, only a few years later, his work for the human race is over, and he has entered on a new career.

Ever since he went to Bonn he has been ailing; he was never strong, apparently, as a child, and his friends have long been anxious about him. A little time ago he seemed to be mending, and we heard better accounts; but since the serious winter began he grew worse, and with the incoming of the new year he passed out of our ken, not yet thirty-seven years of age.

It is not the time to attempt a critical estimate of his work. The greater part of his short life was spent in thorough equipment of himself for the successful quest of the unknown among the most solid and difficult branches of science. Up to the age of twenty-one he studied as an engineer—an admirable training for a physicist, as many can testify. Then he graduated at Berlin, and became assistant to von Helmholtz. Here the writer first made his acquaintance thirteen years ago, when, on calling upon the distinguished professor of physics at the University of Berlin, Hertz did the honours of the laboratory.

During the years at Berlin he published many investigations and theses of a weighty, not to say ponderous, order, and became known in strictly scientific circles as a learned and rising physicist of whom much might reasonably be expected. In 1885 he became Professor at the Technical College of Karlsruhe, and in 1889 he received his call to succeed Clausius in the University of Bonn. But it was during an investigation begun in 1887, at the instance of Prof. von Helmholtz, on some obscure phenomena occurring in induction coil circuits that led him to that brilliant series of experiments which have immortalised his name, and may even be said to have created an epoch in science. July, 1888, saw the publication of the most striking memoir of that series, and at the Bath meeting of the British Association in that same year all the world was apprised of the discovery by Fitzgerald, then President of Section A.

Had it not been for the preparedness of British physicists in this matter Hertz's discovery might have been left to leak out gradually, and be more or less misunderstood for the course of ten or twenty years, as usual. Continental science was in fact by no means ripe for a clear appreciation of these experiments, and even now it is surprising that a continental philosopher should have thus reaped the fruits of the theoretical seed sown in England. However, so it was; Hertz stepped in before the English physicists, and brilliantly carried off the prize. He was naturally and unaffectedly pleased with the reception of his discovery in England, and his speech on the occasion of the bestowal of the Rumford medal by the Royal Society will long be remembered by those who heard it for its simple-hearted enthusiasm and good-feeling. His letters are full of the same sentiment, and there is no doubt that, in addition to being a capable and well-armed investigator, he was also a modest and courteous gentleman. We hoped many times to see him at one of the meetings of the British Association, where he would have been sure of a cordial welcome, but every year he had to excuse himself—once on the ground of military service demanded of him at some autumn manœuvres. It is strange to remember that such a man, with his rare combination of experimental facility with high mathematical equipment, was regarded by his nation, not only in the light of a University teacher, but also as a locomotive unit capable of emitting and receiving bullets. However, this compulsory military service may have conferred upon him some needful relaxation and change of thought, if the discipline was not too trying for his state of health.

In addition to his physical investigations it may not be generally known that Hertz was also genuinely though not obtrusively or actively interested in certain modern discoveries in experimental psychology, and he was a corresponding member of the Society for Psychical Research. Some experiences of his in this connexion had made a distinct impression upon him, and he was prepared to examine into the possible truth of phenomena such as a short time ago would have been by most men in his position scouted as hopelessly improbable or absurd.

It would be a mistake to suppose that his best known research is all we owe to him. He made experiments on the time of contact of elastic bodies of certain shapes before they rebounded, and a minor or collateral discovery of his concerning the curious effect of ultra-violet light in promoting electrical discharge has led to a long series of experiments, and seems likely to afford important assistance in the difficult task of disentangling the relations between electricity and matter—the most promising and suggestive branch of modern physical chemistry.

But the writer does not intend to be drawn into a comment on Hertz's scientific work; he feels too keenly the serious blow which the loss of so young and capable a man entails upon all workers in the same regions of science.

We have lost the skill and power of work, the trained judgment, the patience and store of learning with which he was endowed; and those that are left must close up the ranks and advance as best they can without the aid of that able and friendly co-worker. O. J. L.

REVIEWS.

Recent Researches in Electricity and Magnetism. By J. J. THOMSON, F.R.S. (Clarendon Press.)

This work is intended as a sequel to the great "Treatise on Electricity and Magnetism," first published by Clerk Maxwell twenty years ago. The supreme influence of Maxwell's views in moulding the progress of electrical science since that date is now acknowledged everywhere, and it has been the endeavour of the author of this book to give an account of the more recent electrical researches, both experimental and theoretical, which have been most important in confirming, or in developing, the theory as set forth by Maxwell. It would be too much to expect anyone, even Prof. J. J. Thomson, to succeed in this endeavour to everybody's satisfaction. Only a large committee of experts could possess sufficient authority to decide on the researches which should or should not be included, and it is certain that the limits of a single volume would be too narrow for the purpose. In this book no attempt is made to simplify or explain Maxwell's theory. The reader is supposed to be familiar with Maxwell's treatise, and the equations of the electromagnetic field given in the ninth chapter of the second volume of that work are assumed, and used throughout the present one.

The book consists of seven chapters, three of which—the first, second, and fifth—form comparatively light reading, while the others are highly mathematical. It contains a considerable proportion of purely experimental matter, much of which is now published for the first time in an easily accessible

Digitized by Google

form. The analytical portions of the book consist for the most part of original mathematical work.

The first chapter, entitled "Electric Displacement and Faraday Tubes of Force," is concerned with a physical method of regarding the electric field, which, although not exactly new, has as yet received very little attention. In the science of magnetism, especially when considered from a practical point of view, the use of lines of force to represent the state of the magnetic field is not only important, it seems a necessity. But in electrostatics the corresponding electric lines, or Faraday tubes, are rarely used to denote the state of the medium. Instead of these, the charges on the conductors are considered, and the state of the medium is represented by the variation of a mathematical quantity called the potential. This quantity is a tangible thing in current electricity, because instruments can be made, and are used, to measure it. But in ordinary electrostatics potential is a rather abstract conception, since even the most delicate electrostatic instrument in existence, the quadrant electrometer, is not sufficiently sensitive to measure the potential at a point in the air without altering the thing it is supposed to measure. It thus happens that in electrostatics potential is nearly always considered as a mathematical quantity, and is a conception which an ordinary student has generally much difficulty in properly grasping. To avoid this difficulty Prof. J. J. Thomson suggests the use of Faraday tubes, and says that "this method has all the advantages in vividness which arise from the use of concrete quantities instead of abstract symbols to represent the state of the electric field; it is more easily wielded, and is thus more suitable for obtaining rapidly the main features of any problem; when, however, the problem has to be worked out in all its details, the analytical method is necessary." These statements are no doubt true in the main, but it will depend a great deal on the particular problem considered whether the new method is easier to use than the old. Lines of force are very convenient to consider when their path is pretty well known, as, for instance, in the magnetic circuit of a dynamo or transformer, but when, as in most electrostatic problems, we have only a general idea of where they are, they can rarely be used to give more than a rough notion of the character of the phenomena which occur. Prof. Thomson has been led to the study of these tubes from considering the subject of the passage of electricity through liquids and gases. All the evidence in this connection goes to show that molecular structure is closely allied with electrical charges and the accompanying electrostatic tubes. The tubes of magnetic induction, so familiar to us in the commercial applications of magnetism, under the name of lines of force, do not seem here to have any direct bearing on the phenomena, and are rather neglected by the author during the first half of this book, dealing as it does with a subject to which Prof. Thomson has specially devoted himself, viz., the passage of electricity through gases.

Prof. Thomson commences by defining what he calls the "polarisation" of the dielectric. This is a vector quantity, and means nothing more nor less than the density of the electrostatic lines of force in the field. It corresponds exactly with induction density, which we familiarly represent by B in the science of magnetism, and it is a great pity that Prof. Thomson has chosen the word polarisation, overburdened as it is already with many vague meanings, to represent an exact quantity of this kind. Several mathematical theorems with regard to the motion of electrostatic tubes, and to consequent changes in the components of the polarisation follow; and it is shown that such motion is accompanied by (1) a magnetic force perpendicular both to the tubes and to the direction of motion; (2) a momentum perpendicular to the tubes and to the magnetic induction; and (3) an electromotive force perpendicular to the line of motion and to the magnetic induction. Students of the writings of Oliver Heaviside will be familiar with the perfect analogy which he has drawn between the laws of electricity and magnetism, and with the fact that he has shown that the ordinary law of the generation of electromotive forces by the movement of magnetic lines has an exact analogue in the induction of magnetic forces by the motion of electric lines. Just as an induced electromotive force in any piece of wire is measured by the rate at which magnetic lines of force cut the wire, so the magnetic force induced in any direction by the motion of electric lines is measured by the rate at which these lines cut a unit length measured in that direction. It is not necessary to abandon one of these laws to adopt the other. They are mutually consistent, and each may be shown to involve the other. For a particular class of problems it may however be much more convenient to use only one of these laws. In nearly all cases hitherto considered it has been found preferable to use the former, and to regard electromotive force as being generated by the motion of magnetic lines. This law is accordingly well known, while the view that magnetic force is caused by the motion of electric lines has been altogether neglected. Prof. Thomson finds that the latter law is much the more useful of the two in dealing with the subjects to which the first half of his book is devoted, and proceeds to illustrate this method of regarding electrical phenomena by applying it mathematically and otherwise to the consideration of several cases. The uniform motion of an electrically-charged sphere is first investigated. The magnetic forces in the field, the momentum generated in the dielectric, and the mechanical forces acting on the sphere, are fully worked out, and the author passes on to discuss the theory of rotating electrified plates which have been used by Rowland and others for the experimental investigation of questions which are of the first importance in connection with the electromagnetic theory of light. A detailed examination is then made of the case of a steady magnetic field. The difficulty met with here is to account for the field of a permanent magnet by the motion electrostatic lines of force, in spite of the fact that there are no electrical forces acting in the medium. This difficulty is met in an ingenious manner by supposing the medium to be filled with both positive and negative electrostatic lines, the density of the former being always equal to that of the latter at each part of the field. These lines are supposed to be moving in opposite directions, so that the magnetic forces so generated conspire, while the electric forces oppose and neutralise each other everywhere. The actual motion of these tubes in certain simple cases of magnetised bodies is next discussed, and the more familiar cases of the induction of currents by changes in the magnetic field, or by the motion of the circuit, are considered from the new point of view. The induction of a current in a secondary coil by the variation of current in a primary, can, in this way, be explained without referring to the properties of magnetic lines of force, and the theory of the action is really simpler than that ordinarily given in terms of such lines. The theory of the discharge of a Leyden jar is fully illustrated by means of a number of diagrams, most of which are taken from a former Paper of the author's printed some time ago in the *Philosophical Magazine*. The first chapter concludes with an attempt to use these Faraday tubes to form a mental picture of the processes which accompany the propagation of light according to the electromagnet theory.

The second chapter treats of the discharge of electricity through gases, and occupies nearly two hundred pages of the book. This chapter is one of great value, and forms an excellent summary of the work which has been done on the subject. A large amount of experimental matter is included, and a great number of illustrations are introduced. It is specially rich in references to German researches. Prof. Thomson is to be congratulated on his success in presenting a connected and readable account of such a large number of investigations. The fault of most attempts of this kind is that too little criticism is brought to bear on the description. This defect is not to be found in the present instance, as a very fair amount of critical matter is introduced. Space does not permit our mentioning all the subjects dealt with in this chapter. Some of the chief ones are as follows:—The electrical properties of hot gases, and flames. The phenomena connected with ultra-violet light. The disintegration of charged surfaces and the discharge of electricity by glowing bodies. The researches of Baille, Liebig, Peace, Paschen, and many others, on the phenomena of the spark discharge, and the electric strength of gases. The influence of pressure on the dielectric strength of gases. The discharge of electricity

Digitized by Google

through vacuum tubes and through rarefied gases. The influence of magnets on these phenomena. The effect of electrodes. The velocity of discharge. Crookes's radiant matter. The distribution of potential along the path of the discharge. The arc discharge.

The matter of this chapter is well chosen, and the description very full. When describing the experiments which have been made to find the connection between spark length and potential difference, it would, however, have been an improvement if the experiments made at Messrs. Siemens Bros.' works, and described before the Institution of Electrical Engineers, had been referred to. These experiments were made with commercial apparatus, and with large amounts of power at disposal. They merit attention on this account, as those given in the book were carried out under very different circumstances. The description of the phenomena of the arc discharge is meagre and unsatisfactory, and the matter comprised in §§ 179-193 does not seem of sufficient importance to merit a place in a work of this kind. The theory of the electric discharge given at the end of the chapter is also of too speculative a nature for it to be of much value at present. But these are only small defects in a chapter of great value.

The third chapter on Conjugate Functions is exclusively mathematical, and belongs, moreover, to that part of mathematical physics which should, we think, merely be regarded simply as a section of applied mathematics. It does not help in the least towards explaining any physical phenomenon. No new principles are involved, and the calculations with which the chapter is concerned are confined entirely to such problems as the capacity of conductors of given geometrical shapes. Such calculations are of value when the absolute measurement of some electrical quantity has to be experimentally found; but they do not help to elucidate any physical problem. The chapter possesses the greatest value from a mathematical standpoint, and it forms a full sequel to the corresponding chapter in Maxwell's original work. But, like that chapter, we consider it out of place in a book which is supposed to be devoted to the theory of electricity rather than to mathematical problems connected with the subject.

The fourth chapter is also highly mathematical, but is very different in character from the one which precedes it. It deals with the theory of electrical waves and oscillations, and is, therefore, of immediate use in the explanation of the valuable experiments on electromagnetic waves, which have been made during the last few years by Hertz and his followers. The notation used throughout the chapter is taken without any alteration from Maxwell, and students of the mathematical writings of Mr. Heaviside will be sorry to find that the author makes no criticism of, or reference to, the somewhat simplified system of equations introduced by that writer. We also notice that the very useful word *impedance* suggested by Mr. Heaviside, and now universally adopted, is used by the author of this work in quite a wrong sense. The impedance of a conductor for alternating currents is the ratio of the voltage impressed upon it to the current in amperes flowing through it, thus, if

$$V = R\,C + L\frac{dC}{dt}$$

where V = volts, C = amperes, R = resistance, and L = self-induction, then

$$\text{impedance} = \sqrt{R^2 + 4\,\pi^2\,n^2\,L^2},$$

where n is the number of complete periods per second. But on page 293, and in several other places throughout the book, Prof. Thomson calls R the *impedance* of the circuit, and states that "this term is preferable to resistance, as it enables the latter to be used exclusively for steady currents." Prof. Thomson discusses many new problems in this chapter, and also reproduces from the *Proceedings* of the Mathematical Societies other problems of interest in connection with the subject of electrical oscillations. The chapter comprises close on 140 pages, and forms a valuable work of reference.

The fifth chapter is almost entirely experimental, and forms a very full summary of the researches of Hertz, and of the more recent experiments made in continuation of his important work. A summary of this kind has been much wanted owing to the great amount of experimental matter in connection with the subject, which is to be found scattered among the Proceedings of the various European scientific societies. A great deal of obscurity still surrounds the explanation of many of the phenomena of these oscillations. Prof. Thomson attempts to explain some of them by means of his Faraday tubes. The conception of these tubes proves very useful in certain cases, as, for instance, in the explanation of the fact that the vibrations of the oscillator generally die away much more quickly than those of the resonator. The phenomenon of resonance is, however, not easily explained by these means, and in other respects the Faraday-tube method of explanation leaves much to be desired.

A portion of the chapter is mathematical, dealing with the theory of reflection of electromagnetic waves from walls, metal plates, and wires; the reflection of light from metals, and from gratings; on the scattering or diffusion of electric waves by wires and metal spheres. The chief part of the chapter is, however, devoted to an account of the experiments of Hertz, Trouton, Sarasin and De la Rive, Rubens, Paalzow Ritter and Arons, Lecher, Blondlot, and others, on electrical waves. A fairly full account is also given of the various determinations of specific inductive capacity by means of methods involving the use of electromagnetic waves.

The sixth chapter, on the distribution of rapidly alternating currents, is useful for purposes of reference, but contains very little that is new. The calculations merely relate to combinations of inductive conductors in series or in parallel. The mode of distribution of alternating currents in a single conductor conveying alternating currents is not referred to although a case of some practical importance. The analogous problem of the distribution of lines of force in the iron core of a transformer is, however, treated fully in Chapter IV., and as the problems are identical from a mathematical point of view, the mathematical student will find no difficulty in solving one by referring to the other.

The book concludes with a chapter on the theory of the electromotive intensity in moving bodies, and an appendix referring to the author's experimental work on steam.

Prof. Thomson is to be congratulated on being the author of a book which is well worthy of being called a sequel to Maxwell's great treatise. This volume is certainly the most important electrical book which has been written since the issue of Maxwell's work. W. E. S.

"Clarke's Pocket-Book." For Plumbers, Architects, Sanitary Engineers, &c., &c. By J. W. Clarke and W. Hibbert. (London: Bush and Co. 1893.)

This little pocket-book, with pages no larger than those of Thompson-Thomas's Electrical Tables, contains a large amount of information for plumbers, architects, and sanitary engineers. Fifty-three pages out of two hundred and sixty-six are said to be devoted to electrical tables and memoranda. These are intended either for "plumbers, architects, and sanitary engineers," or perhaps only for the use of the "&c., &c." This part, contributed by Mr. Hibbert, is excellent as a text-book in miniature, and would be very useful to vestrymen, judges, and others who are occasionally called upon to decide important questions of electrical engineering or science, and who have no time for studying long and difficult treatises. It begins with these words: "Nobody knows what electricity is. Its behaviour is, however, well understood, and the line between good and bad work is clearly marked." This is eminently sensible, but why should it be stated in a tiny book into which much useful information should be carefully compressed? There are, in fact, only three, or perhaps four tables in this section, one called a wiring table, in which no account is taken of fall of volts; a fuse table in which the length of the wires is ignored; and a list of the casings of a certain timber merchant. This is followed by another casing list, but it seems to form the beginning of the advertisements. The first part of the book, with which we are not concerned, seems to be full of valuable memoranda.

TELEGRAPH STATISTICS FOR 1892.

The accompanying table and remarks are based upon some elaborate statistics recently published in the *Journal Télégraphique* of Berne:—

England.—The figure given for length of line includes 22,787 miles of private wires, but does not comprise pneumatic tubes nor wires belonging to the Railway Companies. The number of offices does not include those of the Submarine Cable Companies. The number of Hughes instruments includes 46 used on the cables between England and the Continent. Of the "other instruments" 498 are Wheatstone automatics, 129 translators, 78 quadruplex, and 34 Delany multiplex. The total number of instruments includes those used upon private lines. The *personnel* includes the whole postal force as well. The number of paid telegrams includes 20,077 messages at reduced rates sent for account of the Railway Companies. The total number of telegrams includes messages exchanged direct by the Cable Companies without having passed over Government lines. The maximum number of telegrams sent in any one week during 1892 was 1,677,094. The average number of *words* transmitted every week for the press was 12,865,026. The receipts include £120,299 for press telegrams, and £414 for messages at reduced rates sent for the Railway Companies. The revenue from international correspondence includes £56,814 for the rent of special wires leased by the Cable Companies as well as the proportion of the revenue from telephonic communications between London and Paris due to the Government. The "various receipts" include £93,893 for the rent of private wires and £13,447 for wires leased to newspapers. The figure given for cost of establishment is the amount expended during the year 1892 only, and is in addition to the capital sum of £10,130,820 previously spent on this account.

France.—The figures given for the *personnel* are said to be those of the postal and telegraphic services together, owing to the fusion of which also the telegraphic expenses cannot be given separately, but the total number seems far too small to be correct.

Germany.—The "other systems" of apparatus include 10,764 sets of telephone and 50 Estienne instruments. In regard to the *personnel*, the postal and telegraphic services being amalgamated, the number of the staff engaged in the telegraphic service alone cannot be given. The number of unpaid telegrams includes 406,807 railway service messages. The number of telegrams sent abroad does not include 52,844 international service telegrams. The amalgamation of the postal and telegraphic services makes it impossible to ascertain the amounts of receipts and expenses exclusively belonging to the telegraphs.

Italy.—The "other systems" of instruments comprise 17 Wheatstone automatics, 68 Wheatstone receivers, and 9 Baudot. The service messages include messages free of charge from the Royal House to the Holy See, the Presidents of the two Chambers and the Ministers, as well as the ordinary correspondence of the Government, which is not admitted free, but does not include 10,939 messages sent for the railways. The "various receipts" include £8,270, in the shape of *contributions* from the telephone companies.

Norway.—The "other instruments" comprise 13 duplex, 10 quadruplex, 5 Wheatstone automatics, and 41 telephones.

Sweden.—The number of paid messages includes 158,646 messages sent over the railway lines.

Belgium.—The length of lines and conductors does not include 239 miles of line comprising 1,281 miles of conductors laid under water. The number of instruments does not include 105 telephones used for telegraphic transmission. The number given for the *personnel* does not include 3,244 railway servants, &c., who assist in telegraphic work, nor the large number of persons who deliver telegrams without making this service their exclusive occupation.

Holland.—The "other instruments" comprise 2 Estienne, and 369 Bell-Blake, Paul-Bert, d'Arsonval, Theiler, Van Rysselberghe and Berliner telephones.

Switzerland.—The cost of working and maintenance includes £2,022 interest on, and sinking fund of, the cost of establishing the system.

Denmark.—The "other systems" of instruments comprise 7 Wheatstones and 135 telephones. The service telegrams do not include 14,207 international meteorological messages.

India (*British*).—In the number of service telegrams given 85,777 related to the postal service.

RESISTANCE TO ALTERNATE CURRENTS.*

BY E. HOSPITALIER.

In 1886 Lord Rayleigh† published some formulæ enabling us to calculate the effective resistance of a circular conductor through which periodic currents of a given frequency were flowing. Unfortunately the series which give these values becomes so divergent as the diameter and frequency increase that it is practically only applicable within narrow limits. In his Presidential address to the Institution of Electrical Engineers in 1889, Sir William Thomson gave a table for certain diameters, and a frequency of 80, which enables us to greatly extend these limits. It has occurred to me that from the practical point of view it would be convenient to have a simple and concise table which could be used quickly for all diameters and all frequencies, and, assisted by M. A. Potier, I have converted the data given by Sir William Thomson into a simple table, which will greatly simplify and facilitate calculations.

If we denote by R_A the resistance of a circular conductor to alternate currents, and by R_C its resistance to continuous currents, we have the general expression—

$$R_A = k\,R_C \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

k being a numerical coefficient depending both on the frequency 1/T and on the diameter d of the wire. It follows from Sir William Thomson's investigation that for a wire of a given kind this factor k is the same for all values of the product $d^2 \times 1/T$. We can, therefore, draw up a table giving the values of k for each corresponding value of the product of the diameter squared into the frequency. In the following table the diameters are expressed in centimetres, the frequency in periods per second, and the resistivity of copper is taken at 1,597 C.G.S. units. To determine the multiplication factor of the resistance, R_C, of a conductor of d centimetres diameter, we need only multiply the square of this diameter by the frequency in periods per second, and look in the table for the nearest corresponding value of k, and then apply equation (1).

Values for k, the Coefficient of Increased Resistance.

$\frac{d^2}{T}$	k	$\frac{d^2}{T}$	k
0	1·0000	1,620	1·8628
20	1·0000	2,000	2·0430
80	1·0001	2,420	2·2190
180	1·0258	2,880	2·3937
320	1·0805	5,120	3·0956
500	1·1747	8,000	3·7940
720	1·3180	18,000	5·5732
980	1·4920	32,000	7·3250
1,280	1·6778		

For instance, what will be the effective resistance of a copper conductor 2cm. in diameter, traversed by an alternating current of a frequency (1/T) of 80 periods a second, its electrical resistance measured on the Wheatstone Bridge being 3 ohms? We have $d = 2$; $d^2 = 4$; $1/T = 80$; $\frac{d^2}{T} = 320$. We see by the table that the corresponding value of k is 1·0805. Hence

$$R_A = R_C \times k = 3 \times 1{\cdot}0805 = 3{\cdot}2415 \text{ ohms.}$$

If the product d^2/T is not to be found in the table, we can interpolate or make use of the next highest value, in which case we commit an error of excess. The above table is wide enough to determine R_A far beyond the needs of practice. In fact, for the frequency of 150, which is never exceeded in practice, the table gives values of k up to $d = 15$cm., a feature much greater than that which occurs in commercial conductors.

When the quotient d^2/T exceeds 32,000, we shall obtain the effective resistance with great precision by calculating the resistance of the solid conductor as equal to that of a tubular conductor of the same external diameter and thickness equal to $6{\cdot}38\sqrt{T}$ centimetres. All these results relate to pure copper of resistivity 1,597 C.G.S. units. For a metal of resistivity ρ different to that of pure copper and of unit magnetic permeability (which excludes iron,

* From *L'Industrie Électrique*. † *Phil. Mag.*, May, 1886.

Digitized by Google

steel, &c.), the factor d^2/T which enables us to find the corresponding value of k in the table, should be multiplied by the ratio of the resistivity of copper to that of the metal under consideration, that is to say, by $1,597/\rho$, ρ being expressed in C.G.S. units. It is unnecessary to say that these formulæ do not take capacity or mutual induction into account.

I think that this table will be of use to electricians by enabling them to quickly determine whether under stated conditions the factor k is or is not negligible in the conductors they are using.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

C. B. Harness, Director of the Medical Battery Company, J. M. M'Cully, and C. B. Hollier, again surrendered before Mr. Hannay, at Marlborough-street, on Wednesday last, to answer the charge of having conspired together to obtain money by false pretences.

WILLIAM JOHN CLARKE MILLER, registrar and secretary of the General Medical Council, produced the medical registers from 1887 to 1894. He had examined them, and the names of C. B. Harness and C. B. Hollier were not on them. The name of J. M. M'Cully was on the register up to November, 1887, when it was struck off.

Cross-examined by Mr. AVORY: The Medical Council struck persons off the register of their own accord. No appeal from the decision of the Council had ever succeeded. A person struck off the register could not sign a death certificate, could not recover his fees in a court of law, but could practise his profession.

Re-examined: The powers of the Medical Council were regulated by Act of Parliament.

W. R. SELLMAN, otherwise Dudley Towers, who till recently was one of the defendants in the case, further cross-examined by Mr. AVORY, said that the condition of his being released by the prosecution was that he should sign an undertaking (copy produced) not to bring an action against the prosecutors. He only signed the document as a means of escape from the position in which he was placed.

Cross-examined by M'CULLY: He had never known any injury to be done to patients by the use of statical electricity. With the statical chair he should say it would not be possible to hurt a persons finger or shoulder-joint.

This concluded the case for the prosecution.

Mr. AVORY, for the defence, submitted that the prosecution had failed to establish any criminal offence. He used the word "criminal" advisedly, because he very much doubted whether the persons who had put forward the prosecution had appreciated the broad line of distinction between conduct which could give rise to a civil liability and that which could give rise to a criminal prosecution. This was not a *bonâ fide* prosecution at the instance of aggrieved parties, but only part and parcel of the newspaper agitation which for a long time had been going on against the defendant Harness and the establishment at 52, Oxford-street. Civil proceedings were first taken, and when it was found that they were not likely to succeed well then a criminal prosecution was begun, and magistrates and judges had always set their faces against such a course. He could not help thinking that if the true facts of the case had been disclosed process would never have been granted. There were only three possible grounds on which the case could have been held to be a criminal one. The first and only substantial ground on which the case could be supported was that the defendants had been guilty of false representation. The second was the allegation that large sums of money had been obtained from persons by pretending to cure them of complaints from which they were suffering. The third was the allegation that certain persons had complained of having suffered from the treatment they received. As to the first, he submitted that none of the witnesses had proved that any criminal offence had been committed in the eyes of the law. Mr. Terrell, in his opening speech, said that he relied on the advertisements that had appeared, and the statement that Mr. Harness was an eminent electrician, and that the belts he sold were electrical appliances. The application of the term "an eminent electrician" was, however, purely a matter of opinion, and, as a matter of fact, Mr. Harness had patented several electrical appliances. The subject of the belts was the crux of the whole case. On the question of their right to the term "electrical appliance" he would simply refer to the evidence of Dr. Lewis Jones and Mr. Gatehouse, and he would accept as a definition of an electrical appliance that it was something which would generate electricity. Did not the whole evidence of those gentlemen show that the belts, whether connected or unconnected, generated electricity when worn on the human body? The question of quantity was quite another matter, and did not enter into the case. It was obvious when the evidence was looked at that the whole matter was a question between the medical profession and 52, Oxford-street, as to what was the minimum dose of electricity that would produce therapeutic effects. Was that a proper question to submit to a criminal court? The only false pretence alleged was the representation to Mr. Burbage that he was suffering with spine disease, but the evidence of Sellman showed that it was quite another complaint. The prosecution had contrasted the cost of the manufacture of the belts with the price at which they were sold. He could not suppose that they seriously put forward the suggestion that it was a criminal offence to sell an article for five guineas which had only cost 3s. 6d. If they did, the answer would be that every tradesman throughout the country was liable to be indicted, for it did not matter whether the difference between the cost price and the selling price was £5 or £500 or 5d. The fact that money had been obtained from persons that went to the place to be cured could not be put forward as obtaining money under false pretences. In every instance in which money was paid a printed receipt was given, on which was a notice to the effect that the Company declined to guarantee any expectations which might be anticipated from the treatment. It could not be constituted a criminal offence because the defendants sometimes failed. With regard to the third ground of complaint, it was alleged that some injury had been done to persons by the treatment and the wearing of the belts. That did not constitute a criminal offence. It might be the result of unskilfulness or ignorance, but as the law stood it was no criminal offence for a person to undertake to cure a disease, although not a qualified medical man, or to fail when having undertaken to effect a cure. It was only in the case of death that the law could come into action to prosecute. He could show that many cures had resulted from the treatment administered at Oxford-street, and numerous testimonials had been received from grateful patients. There was another matter that he should like to refer to. There were only three persons charged; why were not the other doctors and assistants that were employed in the place charged? Were not they just as much implicated as the three defendants? He thought he should be able to show that the defendants had a *bonâ-fide* belief that the treatment might do good, and, if so, then there was no case against them.

The further hearing of the case was then adjourned for seven days.

Jude and West v. Watson.

This was an action tried before Judge Baylis at Liverpool, in which the plaintiffs, a firm of chartered accountants, sought to recover from Malcolm Walker and Adam West Watson £250 for damages for breach of contract in respect to operations for an attempt to float a company to be called the Walker Electric Lighting and Engineering Company (Limited). Plaintiffs alleged that the defendants engaged their services for floating the proposed Company, which was to include not only the defendants' business but a similar business belonging to a Mr. Hall. After hearing the evidence, the jury found for the plaintiffs against Walker for £5 in addition to £5 paid into Court, and Watson was found not liable. Verdict accordingly.

CORRESPONDENCE.

ELECTRIC TRACTION AND THE BOARD OF TRADE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We should like to be permitted to deprecate your censure on our last week's letter, which we cannot but think unduly severe. The technical press have before now discussed Board of Trade rules with advantage to the profession, and this particular question having been referred to the Council of the Institution of Electrical Engineers, a purely technical body, is surely peculiarly one which may be so discussed. Besides, the technical press reported and commented on the proceedings of the joint committee last June, and cannot now reasonably taboo discussion arising out of those proceedings. We admit that we were not aware that anything was being done by the London Chamber of Commerce, our *Electrician*, to which we naturally look for information on such matters, having been silent on the point. But we are glad to learn the fact now, and trust success will attend the efforts made.

With regard to our "unwarranted insinuation," we look at the matter from a practical, not a sentimental point of view. It appears to us illogical, if not positively indecent, that experts who were advocates last June before the Joint Committee should now be constituted judges of the issue they disputed then, which is what the reference to the Council of the Institution amounts to. It is not necessary to, and we do not, impute unworthy bias, but the experts in question have been accustomed to regard the question from one point of view. They got-up the case for the Telephone Company to the best of their ability, and they doubtless believe themselves right. So, apart from the influence of retainers, they are, and must be, so many advocates against traction. To be otherwise now would be to confess that they pushed their advocacy before the Committee too far last June. We are glad to see that you agree with us that the Board of Trade draft rules are at variance with the Committee's report. That is *the* question. We reiterate that the interests of traction for many years to come are threatened seriously by this proposed stultification of the Committee's report, and that it behoves the profession to see that it comes to nought.—Yours, &c.,

BENNETT AND DRUCE.

44, Fishergate, Preston, January 8, 1894.

[Our correspondents, who admit that they were not aware that anything was being done by the London Chamber of

Digitized by Google

Commerce in connection with the draft Board of Trade rules for electric traction, are not, perhaps, members of the Electrical Trades Section, or being members, are, perhaps, not known to take an active interest in electric traction. The matter has up to the present been discussed by a committee. As soon as this committee has anything to publish, or as soon as they report to a general meeting of the section, it will be time enough to discuss details. Useful work can be, and has been, done by such committees, and a report on their deliberations is no more necessary than on that of the committee of the Institution of Electrical Engineers. The over-head wire rules and other Board of Trade rules have been discussed in our columns after this preliminary stage had been passed.—Ed. E.].

THE PAST YEAR'S WORK.

Brush Electrical Engineering Company.—All classes of electric lighting contracts have been secured by this Company during the past year, which has kept the works fairly employed. This applies particularly to plant for central electric lighting stations, for which the Company have received many important orders. The plant for the lighting of the City of London is nearing completion; and the Bankside station, in addition to the plant originally put down, has received during the year six sets of Raworth-Mordey combined alternating plant, with an aggregate output of 2,500 kilowatts, and the equipment of the various transformer stations is now nearly complete. The original contract for lighting the town of Huddersfield has now been completed, and orders for considerable extensions have been received. Additional plant has been supplied for the central stations at Sheffield, Bournemouth, Hastings, and Woking. Among other central station contracts secured may be mentioned those of Leicester, Lancaster, Dover, Canterbury, Fleetwood, Coatbridge, and the supply of alternators and arc-lighting plant to the Great Northern Railway Company, Holloway, and to Hastings and Blackpool for lighting the promenades on the sea front; alternators, exciters, and transformers to the Bolton Corporation; the complete equipment of the transformer sub-stations for Bristol; and the supply of alternate-current plant for the station at Rugby School. The Company's contracts for exhibition lighting have included this year the supply of the whole of the electrical plant at the Horticultural Exhibition, Earl's Court; and orders for isolated installations have been secured for the lighting of Arundel Castle, Southill Park, Bracknell, Battenhall Mount, Worcester, High Trees Mansion, Redhill, and the supply of arc-lighting plant includes a contract for the Midland Railway Company's station at Leicester. The installation work on shipboard, completed by the Company during the year, includes plant for two vessels belonging to the Pacific Steam Navigation Company; two cruisers for the Argentine Government, &c. Having perfected a system of alternate current-distribution the Company have been giving attention to the further development of their continuous-current plant. With this object in view they have acquired the sole rights for manufacture in this country of the Brush-Desroziers dynamo, and have also begun the manufacture of several classes of two-pole dynamos of high efficiency and moderate price. Important improvements have been made during the year in the Company's Transformers, alternate-current arc lamps and lamp posts, at the same time particular prominence is being given to the supply of plain fittings, switches, and lampholders. The Brush Company made extensive preparations to resume their former position in the incandescent lamp-making branch of the electrical industry. The Brush glow lamps have met with a ready sale. In other departments the Company continues to be occupied fully with large orders, to an extent that taxes their resources to the utmost, notwitstanding the enlargement of their works and the increase of their staff.

Corlett Electrical Engineering Company (Limited).—This firm are the northern agents for Messrs. Crompton and Co., and have carried out a large number of light and power installations in various parts of the country during 1893. A pumping contract has been supplied to the Consett Iron Company (Limited), Durham, in which the power is transmitted from the blast furnaces to the workings of the mine, a distance of nearly two miles. The fact that a plentiful supply of steam was raised from the gases of the blast furnaces determined the position of the generating plant. The first pumping set consists of a series-wound motor, driving by a belt a three-throw ram pump, which delivers water through about 1,000 yards of piping against a vertical head of 110ft. Two other pumping sets consist of motors direct coupled to centrifugal pumps, and deal with large volumes of water at a comparatively small head. The Corlett Company have also supplied a similar pumping plant on the same lines to a colliery in North Wales, where the vertical head is 500ft. A complete lighting plant has been supplied to the Garswood Coal and Iron Company, of Wigan, the generating plant for which is on the surface. The whole of the surface and underground arrangements are included in the lighting scheme. Several similar plants have been supplied to other collieries. A 1,000-light contract was secured for Messrs. McConnel and Co., of Manchester, and several other cotton mill installations have been carried out. The United Alkali Company, at Fleetwood, have placed with the firm an order for a very complete lighting plant for their new works, and the Ince Wagon and Iron Works at Wigan have also been fitted throughout for the electric light, Crompton-Pochin arc lamps being used. The firm have some important contracts in hand approaching completion.

Messrs. Doulton and Co.—In addition to their usual large trade in telegraph and telephone insulators, and pottery parts for electrical apparatus, Messrs. Doulton and Co. have received numerous orders for their patent stoneware conduits for underground cables, which have been supplied to several London and provincial companies. A description of this conduit was given in a recent issue of *The Electrician*. The firm have gratifying proof of its growing popularity from the receipt of several large orders from important works shortly coming on. Another specialty for which the firm is well known is their vitrified stone insulators for bare copper mains, for which they have designed special manufacturing plant. Recent contracts for these insulators include Oldham, Aberdeen, &c.

Messrs. Paterson and Cooper.—This firm have during the past year been fairly well employed, and they have fitted a number of vessels with complete outfits of electric lighting plant, including the "Matin," "Princess Beatrice," "Laurentian," "Empress," "Zaize," and "Noir-el-bahr," in addition to supplying complete direct-driving sets for the s.s. "Premier," of the Canadian Pacific Service, and for other vessels. A large number of installations have also been carried out. During the year Admiralty contracts of considerable size have been executed, and Messrs. Paterson and Cooper have introduced their new patent 5-ampere lamp, which has met with a favourable reception, as have also their improved electrical measuring instruments. Several important contracts are in hand for the New Year, which, however, does not, in the opinion of the firm, offer any very promising prospects.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "'The Electrician' Electrical Trades' Directory and Handbook" is in preparation, and will shortly be published. *New names, alterations of addresses, &c., should be sent in at once.* Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"Electrical Engineering Formulæ," a pocket-book, by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

Tenders Invited.—The County Borough of Hanley invite tenders for the electric light wiring and fittings for the various Corporation buildings, of which particulars are given in our advertisement columns, and also for electricity meters, switches, testing, and measuring instruments, &c. Separate tenders must be sent in to Mr. Joseph Lobley, the borough engineer, not later than Monday, the 29th inst.

———— The Corporation of Edinburgh invite tenders for work in connection with contracts Nos. 1, 2, 3, and 4 for their electric lighting station in Torphichen-street, Edinburgh. Copies of any of the specifications can be obtained from Prof. A. B. W. Kennedy, 14, Old Queen-street, Westminster, S.W., and tenders, addressed to Mr. W. Skinner, Town Clerk, City Chambers, Edinburgh, must be in not later than the 30th inst. It is a condition with these contracts that tenders will only be considered from firms who are actual manufacturers of the whole or an important part of the work for which they estimate. Further particulars will be found in our advertisement columns.

———— The Corporation of Cheltenham invite tenders for supplying and erecting engines, dynamos, and boilers at their electric light station. Tenders must be in by Tuesday, the 23rd instant.

Digitized by Google

TENDERS ACCEPTED.—The tender of Mr. J. S. Brown, of Oxford-street, Swansea, has been accepted for lighting the Swansea Docks, for the sum of £649, the contract to last for five years. A large number of tenders were received, the highest being £927.

——— The Town Council of Halifax have confirmed the various contracts for the electric lighting works recommended for their acceptance by the Electric Lighting Committee, which will be found in our issue of December 15th. and have in addition accepted the tenders of Messrs. Pollit and Wigzell (Limited) for condensers at £225, of Messrs. Robey and Co. (Limited) for two horizontal engines for exciters at £327, and of Messrs. H. Jenkinson and Co., Halifax, for sub-stations, at £79. 15s. 8d.

APPOINTMENTS VACANT.—The Wolverhampton Corporation require a draughtsman and assistant at their electric light and power works. Applications must be sent in to Mr. F. Harman Lewis, borough electrical engineer, Town Hall, Wolverhampton, not later than January 27th. The Corporation also require an outdoor foreman and linesman, for which post applications must be sent in not later than the 27th inst. Further particulars will be found in our advertisement columns.

DISSOLUTIONS OF PARTNERSHIP.—Mr. Fulwell has retired from the firm of the Coventry Electrical Engineering Company, and the business is now carried on by Messrs. Eaves and Butlin.

——— The firm of King, Brown and Co., electrical engineers, has been dissolved by mutual consent, Messrs. A. B. and D. G. Brown retiring. The business will be carried on under the name of King and Co., the partners being Messrs. W. F. King, A. Ogilvie, and A. Wilson.

MESSRS. DAVEY, PAXMAN AND CO.—Mr. James Paxman, who has for many years been the sole proprietor of Messrs. Davey, Paxman and Co., engineers, Standard Ironworks, Colchester, has taken into partnership his son, Mr. William Paxman, from January 1st. The title of the firm will remain unchanged.

MESSRS. WHEATLEY KIRK, PRICE AND GOULTY.—From January 1st Mr. Sherley Sherley-Price, son of Mr. H. Sherley-Price, has been admitted as a partner in the firm.

EXTENSION OF PREMISES.—The Electrical Installation Company (Limited) have, owing to the increase of business, found it necessary to extend their premises, and are moving into additional offices at 66, Victoria-street, S.W., which will be the address for all general office communications. The Company have started new works in Pimlico.

GOVERNMENTS AND THE TELEPHONE.—In our summary of electrical events for 1893 we omitted to place on record the purchase by the Austrian Government of the rights, &c., of the Telephone Company of Austria, which were taken over by the Government as from January 1, 1893.

MAGNETIC DECLINATION.—We have received from the *Colliery Guardian* a map, well got up, varnished, and mounted on rollers, showing lines of equal magnetic declination or variation of the compass corrected to the beginning of the new year—that is, to January 1, 1894. The lines, which are shown in red on the map, depend, as in several past years, on the magnetic survey of the kingdom undertaken by Profs. Rücker and Thorpe. The rate of annual decrease at Greenwich is thus about 7 minutes yearly, and it is much the same over the area covered by the map, as mentioned in the note thereto attached.

CORRECTION.—We last week notified that the contract for lighting the new premises of the Bank of Scotland had been secured by Messrs. Rashleigh Phipps and Dawson ; the name should have been Messrs. Rashleigh Phipps and Co.

ALUMINIUM.—The Cowles (Aluminium) Syndicate Company (Limited) send us their latest circulars giving prices and particulars of their aluminium bronze sheets, rods, ingots, castings, forgings, &c. These circulars can be obtained on application to the Company at Milton.

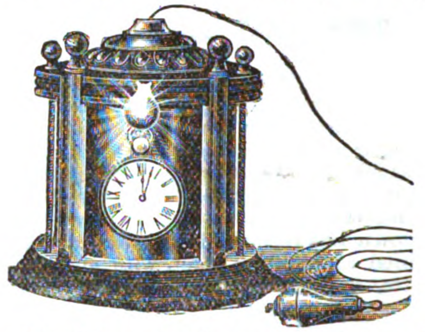
THE CONSOLIDATED TELEPHONE COMPANY.—This Company are issuing revised circulars relating to their Gower-Bell Telephones, and accompanying the illustrated printed particulars are valuable testimonials, one of which is from Spain, which speaks very highly of the Gower-Bell telephones erected nearly 13 years ago, and which, after continual service during this long period, still give every satisfaction. These telephones, too, were the first to be used in Spain, and were those with which brilliant tests were made at great distances.

MESSRS. MATHER AND PLATT'S CATALOGUE.—We have received from Messrs. Mather and Platt illustrated price lists of their Edison-Hopkinson dynamo, Edison-Hopkinson motor, "Manchester" dynamo, "Manchester" motor, and of their alternator. Several improvements have recently been made in these well-known machines.

MR. E. R. DOLBY, C.E.—Under the superintendence of Mr. Dolby, acting as consulting electrician, the electric light has recently been installed at Harrington-gardens, for Mr. S. V. Morgan, Messrs. G. Trollope and Sons being the contractors (137 lights) ; at the Economic Life Assurance Society's office, for which Messrs. Baily and Grundy were the contractors (80 lights) ; and Messrs. Strode and Co. are the contractors for the lighting of "Saratoga," Forest Hill, for the complete installation of 104 lights, including a Crossley gas engine, Mather and Platt' dynamo, and E.P.S. cells.

SMOKE ABATEMENT.—Reference has recently been made in our columns to a smoke and fumes annihilator, invented by Mr. Samuel Elliott, of Newbury, Berks., of which a successful demonstration was given at the Birmingham Mint a week or two ago. Negotiations are in hand for the sale of the American patents, for which a tempting offer has, we learn, been made.

ELECTRICAL NOVELTIES.—An electrical novelty is introduced out by Messrs. Robertson and Co., of 234, Sauchiehall-street, Glasgow, who have on sale an electric night-light, made of best quality nickel plate, with walnut top and base. These night-lights are fitted with three dry cells, with a fairy glow lamp in front, and



are supplied with 12 feet of silk-covered wire cord. The fairy lights are guaranteed for three months. They are supplied with a recess for a watch, over which the glow lamp throws its rays. The illustration shows the novelty complete.

TIME CHECKS.—The illustration below shows the Bristol electric time check (Miles' patent), of which Messrs. King, Mendham and Co., Bristol, are the makers. The time check is specially designed for use in factories and workshops for checking workmen's time, and is the only apparatus of the kind actuated and controlled by electricity. The men are provided with checks, which, at appointed times, are dropped into the slots in the apparatus, which checks are subsequently removed, the numbers registered, and the checks placed upon a board ready for the men to take when next leaving work. The slot in case is electrically opened at appointed times, the time of opening being governed by a clock specially fitted with adjustable contacts, and directly the circuit is broken the slot is closed. If the workmen are in time the checks fall into the proper

receptacle at the base of the apparatus, or through a specially-made opening into the offices behind. If the workman is late, the check falls into a drawer in front of the case, and he then learns that he is late. As the time approaches at which, by the rule of the works, he is re-admitted, the next slot opens and his check is received. The time check is fitted in a polished wood case, and can be provided with as many slots as are found to be necessary. Usually two slots only are required, marked "Early" and "Late," as shown in the illustration. The apparatus is supplied in a portable form, and can be used either occasionally or regularly. It is claimed that there is no special clockwork and no complicated parts ; that no fixing is required; that one clock can be fitted to work as many time checks as are necessary, and that any ordinary clock can be adapted for use for the apparatus.

THE ENGLISH ELECTRIC CARBON COMPANY.—It is a matter for regret that all the carbons used in England for arc-lighting have hitherto been imported from abroad. The best quality, which must be used to attain the best results in this system of lighting, come from the Continent, while the inferior quality used with much less satisfactory results are an American product. Under the title of the English Electric Carbon Company (Limited), a company has been formed to enter commercially into the manufacture of electric light carbons. The chairman of the Company is Mr. John H. Darby, the Managing-Director of the Brymbo Steel Company (Limited), and amongst the Directors are Sir H. B. Robertson and Mr. J. C. Edwards, of Ruabon. The secretary and manager is Mr. T. Graham Littleboy. The factory has been erected at Brymbo in North Wales, on the most modern lines, equipped with special machinery and appliances, and is now in full operation. The Company have secured the rights to all the trade secrets and methods of manufacture of one of the best carbon makers on the Continent. A laboratory and testing room are provided, and the utmost care is used in the selection and treatment of materials and the testing of the carbons. Sizes from 8mm. to 20mm. are quoted in this Company's list.

THE "ENGINEERING MAGAZINE."—A special issue of this magazine is made for January, and is entitled "The World's Fair in Retrospect." The number is crowded with photographic views of the World's Fair, interior and exterior views of the various buildings, and the chief exhibits; and, in addition, contains the usual critical notices on architecture, civil engineering, railways, electricity, &c. Altogether, the number is, probably, the handsomest production of the kind ever published. The photographs and the printing are alike excellent throughout.

MACHINERY AND HARDWARE CATALOGUE.—Messrs. J. H. Hackworth and Co., successors of the Machinery and Hardware Company, forward us their new catalogue of machinery by the principal makers. A large variety of machines and apparatus are illustrated, and very complete particulars are given as to prices, sizes, &c.

ELECTRO-HARMONIC SOCIETY.—A smoking concert will be held on Friday, the 26th inst., at the St. James's Hall Restaurant, Regent-street, W., at eight o'clock. A varied and excellent programme is provided.

ENGINEERING AND MACHINERY DIARY, 1894.—This is the title of a new diary, compiled by Mr. J. S. Jeans, and published by Messrs. Straker and Sons, London. The contents include a variety of formulæ, tables, &c., and other information of use to the engineering trades.

NEW YEAR CALENDARS.—The Direct Spanish Telegraph Company send us a highly-illuminated hanging pad calendar, in which an improvement is shown over the ordinary issues of this kind by the figures being printed in very bold type, which can be seen at a distance. It is printed in Spanish.——A useful calendar, paper weight and pen brush combined, is sent by the Western Union Telegraph Company.——Messrs. Willcox and Co. send us their useful hanging pad calendar, which, in addition to the usual information, contains illustrations of a variety of specialties for which the firm are well known.——New Year's greetings come from the staff of the Commercial Cable Company in the shape of an ornamental card, on which the famous yacht "Vigilant" forms the centre piece, with horse-shoe mount.——The Indo-European Telegraph Company also issue a pad calendar, upon the back of which is printed an exhaustive tabular sheet of tariffs by the Company's cables.——Messrs. Clarke, Chapman and Co. is another firm of electrical engineers who adopt the hanging-pad calendar, upon which effective announcements are printed.

BATTERSEA.—A motion made at the last meeting of the Vestry to appoint a new special committee to inquire into the electric lighting question was adopted, and the committee was appointed.

BERMONDSEY (LONDON).—The desirability of lighting the Public Baths, Town Hall, and Free Library by electricity has recently been discussed by the Vestry, but the subject has to be shelved owing to the absence of funds.

BIRMINGHAM.—A *conversazione* of the Birmingham and Midland Institute was held on Tuesday evening last, at which there was an exhibition of machinery, models, and electrical appliances by the Birmingham Electric Supply Company (Limited), who supplied current for working the same from the street mains. The arrangements were carried out by Mr. J. C. Vaudrey, the Company's engineer. Amongst the exhibitors were Messrs. Evered and Co., Messrs. F. and C. Osler, the Callender Company, Messrs. Ferranti, and Messrs. Chamberlain and Hookham. Included in the exhibition were a number of stands where machinery in motion, driven electrically, formed a great attraction. Electric cooking and heating were shown, and the exhibition, which closes to-night (Friday), has attracted much attention and has been very popular.

BLACKPOOL.—A discussion took place at the last meeting of the Town Council, and the recommendation of the Electric Lighting and Tramways Committee that Mr. R. Hammond should be asked to advise the Corporation upon some extensions that were in contemplation, was approved. It is contemplated that about £20,000 will be required for the extensions which will be undertaken.

BRAY.—The Electric Light Committee have advised the Township Commissioners to enter into negotiations with the electric-light contractors for the purchase of their plant, &c.

BRISTOL.—A letter has been received by the Sanitary Committee of the Corporation from Mr. George White, secretary to the Tramways and Carriage Company, recommending the use of the Overhead system on the proposed extension of the tramways from St. George to Kingswood. We understand the Committee have the matter under consideration, and are likely to visit Walsall, Darlaston, and Wednesbury in order to inspect the tramways systems there, where about 8½ miles in all are worked by electricity.

BURY.—A proposal by Mr. Bentley at the last meeting of the Town Council, that it was desirable that the Electric Lighting Committee should include in their scheme the introduction of a refuse utilizer, was seconded and carried.

CHESTER.—Some time back the Town Council proposed the selection of the Hop-Pole Paddock as the site for the electric-lighting station for the borough, but the Dean and Chapter of Chester Cathedral recently memorialised the Council against the proposal. It was pointed out at the meeting that the Council had some time back purchased the land from the Dean and Chapter, and it would be necessary now for the Council to pay £3,000 or £4,000 for ground suitable for a site. An expert was to be engaged by the Council to report upon the site and its suitability.

CHICHESTER.—The electric lighting committee of the Town Council have passed a resolution, which has been confirmed, instructing Messrs. Kincaid, Waller and Manville to report to the Council on an electric lighting scheme for the city.

CHURCH LIGHTING.—The Notting Hill Electric Lighting Company have received a very favourable report from the Trustees of Denbigh-road Wesleyan Chapel, Bayswater, where the electric light has been recently installed. The Trustees say that the electric light has proved a great improvement upon the previous lighting arrangements, and that they are about to extend the installation to the Sunday school rooms.

DORCHESTER.—A report has been received by the Town Council from Mr. Newton, of Taunton, who was commissioned to prepare a scheme for the public lighting of the town by electricity. He estimates that the capital outlay would be £6,000, and the annual upkeep about £1,300. In the scheme it is proposed to utilise water-power to some extent. After discussing the matter the Council unanimously decided that it was not, for financial reasons, at present advisable to proceed with the scheme.

DUBLIN.—At the Gaiety Theatre (Dublin) the pantomime of "Little Red Riding Hood" has been successfully produced. One of the scenes is the Glow Worm Glen, and quite a realistic effect is brought about by the introduction of electric glow lamps. Among the ferns and undergrowth about the roots of the trees in the scene numerous tiny incandescent lamps are fixed. These light up and darken alternately in imitation of the glow worm, and in the trees above some small lamps are so fixed as to give the idea of fireflies. This part of the work, which is charmingly effective, has been carried out by Messrs. Porte, Syke and Co.

ELECTRIC ORGANS.—Messrs. Brook and Co., of Glasgow, are erecting in the Dixon Hall, Govan Hill, a large organ to be worked by electricity.

GLASGOW.—The Trustees of the Clyde Navigation Trust have been asked by their Committee of Works to adopt a scheme of electric lighting for Cessnock Dock, and designs and tenders may be invited for an electric power installation for working nine electric cranes, three for each of the berths on the south quay. If the electric cranes prove successful additions will be promptly made, so that the remaining quays may be furnished. At the meeting of the Trust, where these proposals were discussed, after deferring the consideration of that portion of the report dealing with crane appliances, the minutes were confirmed.

GUILDFORD.—At the last meeting of the Town Council the question of opposing the electric lighting Order of the Holloway Electricity Supply Company (Limited) was discussed, and the matter was ultimately referred to the Electric Lighting Committee to be "dealt with."

HALIFAX.—After considerable difficulty a suitable site for the new electricity works has been found, and the purchase was confirmed on Wednesday last by a special meeting of the Town Council. The area is over 4,700 yards, and is so favourably situated that coal can be shot direct into the furnaces from the railway siding, and water is plentiful. The site is known as the Park Mills, situate nearly 400 yards from the site originally selected in Cripplegate.

Digitized by Google

HEYSHAM.—A meeting of the ratepayers of the newly-formed district of Sandylands, near Morecambe, was recently held, and the estimate of the Morecambe Gas and Morecambe Electric Light Companies were compared. After discussing the matter it was unanimously decided to adopt the electric light. The installation is expected to be completed in about two months.

LEEDS.—It seemed the general opinion of the members of the City Council at their last meeting that it was advisable to copy the plan adopted by the Edinburgh Corporation in transferring the working of the Leeds Tramway system to a private company under guarantees. Opinion was divided as to whether electricity or cable haulage should be adopted.

MILDENHALL.—The extensive Lark Roller Flour Mills, Mildenhall, have been installed throughout with the electric light, the plant including two "Hercules" turbines in place of the old water wheels. The contract has been carried out by Messrs. W. J. Crampton and Co., of Cambridge.

MONMOUTH.—As mentioned in our last issue, the estimates for the electric lighting and drainage scheme have been separated, and in round figures, £8,000 is the sum required under the electric lighting tenders. A discussion ensued at the last meeting of the Town Council as to the practicability of using the water of the river Wye, and it was ultimately decided to obtain the services of an independent hydraulic engineer to report to the Board upon the working of turbines before putting the work in hand, for which a Provisional Order has been applied for by the Council.

RADCLIFFE.—A sub-committee of the Local Board have reported that the result of their visit to the electric lighting works at Morecambe, Blackpool, Bradford, and Leeds induced them to strongly advise the adoption of the electric light for the district; but, before taking further steps, they recommended the Board to consult an electrical expert as to the system most likely to suit the requirements. The report of the Committee was adopted, and the matter is, we understand, to be energetically proceeded with.

ST. PAUL'S CATHEDRAL (LONDON).—The subject of lighting this cathedral by electricity is engaging the serious attention of the Dean and Chapter. The gas lighting is pronounced fairly satisfactory, but the process of lighting the many burners fitted in the cathedral is a very tedious one, and this and other advantages of the electric light will doubtless ultimately induce the Dean and Chapter to decide upon the latter illuminant.

SALFORD.—Tenders have been accepted for work in connection with the electric lighting scheme. Mains are first to be laid in those thoroughfares from which the largest number of applications for the light have been received.

STIRLING.—At an important conference of business men, held recently, it was resolved to ask the Town Council to abandon its resolution opposing the application of the Caledonian Electric Supply Company for an electric lighting Provisional Order. It was stated that the Company intend, if the Council withdrew their opposition, to make Stirling the centre for supplying the electric light to Bridge of Allan, Alloa, Alva, and other places in the district. The Town Council have, by the casting vote of the Chairman, resolved not to grant the application of the Caledonian Electric Supply Company for a Provisional Order to supply the district with the electric light. The Company will, we learn, proceed with their application, which has received considerable support.

TREHARRIS.—The gas supply in this town is the subject of much complaint, and at a recent meeting of tradesmen it was suggested that the Ocean Coal Company should be asked to supply the district with the electric light.

WAKEFIELD.—Mr. Robert Hammond has presented his report to the Corporation of Wakefield upon the proposed establishment of municipal electricity works in the city. After pointing out the extensive undertakings carried out by many of the local authorities in the country, Mr. Hammond sets out in detail statistics which will be found of service to all authorities contemplating the introduction of the electric light, both for public and private use. He recommends that the Kirkgate site, which the Corporation propose to adopt for their electric lighting station, be substituted for a more eligible position, where ample room for extension is available. He points out that the Corporation have two such positions to select from—one at the proposed sewage works, and the other at the sanitary depot. His estimate of the ultimate cost is based upon the establishment of the works upon the sewage site. Mr. Hammond recommends the high-tension system of supply on the 3-wire system.

WALSALL.—A proposal was before the Town Council on Monday last that a portion of the old Wolverhampton-street Gasworks, including the old boiler, retort and purifying houses and chimney stack, should be set apart for the proposed electric lighting station, and it was further proposed to increase the amount to be borrowed for the electric lighting scheme from £19,650 to £21,900, to cover the additional cost of land and buildings to be taken over.

WEDNESBURY.—Complaint is made of the proposed increase in the price of gas for public lighting, and also of its quality, and suggestions are made that the Town Council should consider the subject of introducing the electric light.

WHITEHAVEN.—At the last meeting of the Harbour Trust the Chairman said that the generating plant had proved sufficient for applications for the electric light received to the present time, but there was no doubt additional plant would shortly have to be put down. They had already applications on hand for anadditional 480 lamps, and the plant was now nearly running to its utmost capacity. The accounts to be presented in March would be so satisfactory as to justify the trustees in duplicating their plant. The private demand for the light had considerably exceeded all expectations.

WIGAN.—A circular has been sent round to tradesmen in the town quoting the terms on which the Corporation are prepared to supply electric current, and asking what support the recipients were willing to give the scheme if carried out by the Corporation.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

December 28, 1893.

24,926. W. BRIERLEY. Halifax. Improvements in the method of, and means employed for, completing electric circuits. (P. Weber and J. Heinrich, Germany.)*

24,946. F. S. RANDALL, E. PACKARD, J. ROBINSON, and W. J. CHANINEL. London. Improvements in coverings for electric wires.*

24,948. E. C. DE SEGUNDO and W. DERHAM. London. A time electric switch.*

24,951. F. H. NALDER, H. NALDER, C. W. T. CRAWLEY, and A. SOAMES. London. Improvements in electrical measuring instruments.

24,966. R. J. LATIMER. London. Improvements in, or relating to, the production of electrotype plates for printing purposes.

December 29, 1893.

24,979. W. THOMSON (Baron Kelvin). Glasgow. Improvements in instruments for measuring and recording electric pressures and currents.

25,009. F. W. SCHINDER. London. Electric heater, and its application to electric cigar lighters.

25,013. F. HALLOWS and F. J. BEAUMONT. London. Improvements in or connected with apparatus for feeding carbons in electric arc lamps.

25,016. H. H. LAKE. London. An improved rosette for electric wires. (W. B. Rand, United States).*

December 30, 1893.

25,056. F. LYST. London. Improvements in incandescent electric lamps.

25,082. J. W. T. CADETT. London. Improved means for arranging and intensifying the magnetic fields of dynamo-electric machinery.

COMPANIES' MEETINGS AND REPORTS.

Fowler-Waring Cables Company (Limited).

The Directors' report, to be presented to the shareholders at the fifth ordinary general meeting, to be held at the offices, 32, Victoria-street, London, S.W., to-day (Friday), at twelve, contains the following :—

The Directors have passed their fees for this year to the credit of this account, which thus shows a net profit of £1,990. 5s. 3d. Out of this profit the Board proposes to write £1,329 off the value of shares in other companies, which now stands in the balance-sheet at £2,115, thus reducing this item for next year to £786, at which price they may safely be left for the present, and to carry forward the balance of £661. 5s. 3d. to the credit of next year. The shares in other companies were taken in part payment of contracts, and practically represent the profit on cables supplied. The Directors believe that they will earn dividends, and become saleable at par or over in due course ; but in the meantime they deem it desirable to reduce the estimated value. On turning to the balance-sheet, shareholders will notice that the Directors have placed the whole of the fees, hitherto credited, but not drawn by them, to the credit of that account, and they have thus been able to strike out the balance of loss as it appeared in last year's balance-sheet, and to write off £1,209 4s. 10d. from the preliminary expenses. No allowance has been made for depreciation of plant and machinery, but all has been fully maintained and repaired from revenue. The stock has been taken with great care, and valued throughout at or below cost.

The Company's business has continued to increase, the sales being considerably in excess of last year, whilst the gross profits have, on the whole, and notwithstanding severe competition, been well maintained. The Directors recently made a temporary issue of £10,000 in Five per Cent. Debentures, repayable in September, 1894. With the exception of £1,000 taken by one shareholder, the whole of this amount was either subscribed or guaranteed by Directors. In view of the immediate necessity of providing additional capital to meet the growing business of the Company, and to pay off the debenture debt, the Directors are negotiating for a fresh issue of £25,000, on Debentures to be secured against the general assets of the Company, which in the meantime have largely increased, and afford, in the opinion of the Board, ample security for such an issue. Meanwhile, the Directors are still confident that, with sufficient capital and ordinary fortune, the Company's affairs must continue to improve.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

ELECTRIC EXPLOITATION COMPANY (LIMITED).—This Company was registered on January 4th, with a capital of £25,000, in £1 shares, to carry into effect an agreement with Max Sussmann for the acquisition of certain existing inventions relating to manufacture, and to deal in, secondary battery plates, secondary battery lamps and dry electrolyte for secondary batteries, and other inventions relating to the generation, storage, distribution and employment of electricity, and to carry on the business of an electric light, heat and power supply company in all or any of its branches, electrical and mechanical engineers, lamp manufacturers, metal and wood workers, metallurgists, &c. The subscribers, with one share each, are :— A. H. Tredwen, H. T. Godrich, E. J. D. Hewitt, W. Wood, J. A. Buchanan, V. C. Doubleday, and P. C. Atkins. The first Directors are :—John A. Buchanan and V. C. Doubleday.

PORT BEIRA PIER, TRAMWAY, AND TELEGRAPH COMPANY (LIMITED). This Company was registered on January 6, 1894, with a capital of £150,000, in £1 shares, to carry into effect an agreement between Joan R. Davies and Herbert Edwards, to acquire telegraphs, telephones, electric lighting, heating, and power works, &c. The subscribers, with one share each, are :—O. Heindorf, A. C. Heindorf, W. H. Talbot, G. F. Rooper, R. W. Elder, Ernest Roney, and H. Bowles. The first Directors are :—R. Bensusan, Count de Mendia, C. Algernon Moreing, and (after allotment) R. G. Webster M.P.

RUGBY SCHOOL ELECTRIC LIGHTING COMPANY (LIMITED.)—The statutory return of this undertaking, made up to November 28th, has been filed. 70 shares out of a nominal capital of £5,500 in £50 shares have been taken up, upon which a call of £25 per share has been made, and £1,750 paid in respect thereof. The shareholders are the Head Master and Assistant Masters of Rugby School, no outsiders being admitted.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LTD.).— Evidently the intended purchase of the business of an American company of a similar name has not yet been completed, as, at the time of making up the statutory return recently only the seven signatories' shares had been subscribed for, no calls having been made.

TELEGRAPH IMPROVEMENT COMPANY (LIMITED).—The annual return of this Company, made up to December 22nd, has been filed. 15,006 shares out of a nominal capital of £100,000 in £1 shares have been taken up, 15,000 of which were issued as fully paid, while the full amount has been called and paid on the remainder.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended January 7th, were £990, as against £998 for the corresponding period of last year, being a decrease of £8. The total receipts for the half-year amount to £990, as against £998 for the corresponding period of 1893, a decrease of £8.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 3s. per share (free of income-tax), being at the rate of 3 per cent. per annum, for the quarter ended December 31st last (such dividend to be payable on and after the 24th inst.), carrying forward £3,080. 10s. 10d.

DOVER.—The *Dover Express* states that there was a fair demand for the Dover Electric Light Company's shares, and that although all were not applied for, sufficient capital was forthcoming to justify the Company in proceeding with the works.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on February 1st next of the interest due January 31st on the Company's Four per Cent. Mortgage Debenture Stock. The register will be closed from the 27th to the 31st inst., both days inclusive.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for December, 1893, amounted to £20,800, and from January 1 to December 31, 1893, to £269,200. In the corresponding months of 1891 and 1892 the amounts were £282,600 and £266,400 respectively.

PORT BEIRA PIER, TRAMWAY, AND TELEGRAPH COMPANY (LIMITED). The prospectus has been issued of a company bearing the above title, with a share capital of £150,000, in £1 shares. The Company is formed for the purpose of acquiring and working privileges and concessions granted by the Mozambique Company for the construction of piers and landing stages, tramways, telegraphs, and telephones in the port and town of Beira on the East Coast of Africa.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—It is stated by the *Financial News* that on January 2nd interest was paid on the bonds of this Company, which was organised in 1893 to take over the gas and electric light works of the cities of Salt Lake and Ogden, in Utah, U.S.A. (See also paragraph under "Statutory Declarations.")

WESTERN UNION TELEGRAPH COMPANY.—The following is the report of this Company for the quarter ended December 31st last :—The condition of the Company at the close of the quarter ended September 30th last is as under :—

Surplus July 1, 1893, as per last quarterly report, ……		\$6,888,457 66
Of which (on account of sundry fractional and other items aggregating $16\frac{38}{100}$ shares) there has since been capitalised by the issue of additional capital stock, for the purpose of equalisation, and that the outstanding capital stock issued shall be exactly \$94,820,000, …		1,638 00
Less which leaves ……		6,886,819 66
Net revenues, quarter ended September 30, 1893 ……		1,749,615 22
		\$8,636,434 88.
From which, deducting for dividend of 1¼ per cent. paid October 15th ……	\$1,184,992 50	
Interest on bonded debt ……	223,262 25	
Sinking funds ……	20,000 00	
		\$1,428,254 75
Left a surplus October 1, 1893, of ……		\$7,208,180 13
Surplus October 1st, as above ……		\$7,208,180 13
The net revenues of the quarter ended December 31st instant, based upon nearly completed returns for October, partial returns for November, and estimating the business for December, will be about …		1,550,000 00
		\$8,758,180 13
From which, appropriating for interest on bonds ……	\$223,262 25	
Sinking funds ……	20,000 00	
		243,262 25
		\$8,514,917 88
It requires for a dividend of 1¼ per cent. on the capital stock issued ……		\$1,185,000 00
Deducting which leaves a surplus, after paying dividend, of ……		\$7,329,917 88

In view of the preceding statements, the Committee recommend the adoption by the Board of the following :—*Resolved*, That a dividend of 1¼ per cent. on the capital stock of this Company be hereby declared payable on and after January 15th next, to stockholders of record at the close of the transfer books on December 20th instant. *Resolved*, That for the purpose of such dividend the stock books of the Company be closed at three o'clock on the afternoon of December 20th instant, and be reopened on the morning of January 2nd next. (The dividend order, when properly filled in, may be collected through any bank on or after January 15th).

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended January 5th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £3,037.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ended December 31st were £2,563, as compared with £2,706 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 818.—Vol. XXXII. FRIDAY, JANUARY 19, 1894. PRICE SIXPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The practice of allowing a coroner's jury to append riders to their verdicts often gives opportunity for the expression of sensible opinions, but it is not without serious danger. The inquiry into the death of a man at the Blackfriars transformer station resulted in a verdict which calls for no remark, but was accompanied by the recommendation of the use of rubber gloves. We hope that any harmful result of this well-meaning but mistaken idea may be over-ruled by a simple and effective regulation by the Board of Trade. On this occasion the supply company has not made the smallest attempt to shelter itself behind a pair of rubber gloves, and is ready to condemn the false security offered by this cheap but ineffectual precaution. We threw out a suggestion that barriers or doors in such stations might be interlocked with the switches; but this may be difficult to arrange in practice. Major Cardew's proposal for a red pilot lamp on each transformer seems excellent at first sight; but it must be remembered that if the small transformer for the lamp, or the fuse, or the filament of the lamp, fails, the attendant would think that the current had been shut off, and that there was no danger. Any device of this kind must be absolutely trustworthy. We understand that none of the men put in charge of the London Corporation's sub-stations have been in their service for less than four years, and that the man who was killed had been with them for six years. It is estimated that he had changed-over sets of transformers on about one thousand occasions before the accident. Under these circumstances, what would be the use of a printed card, "Danger! Please see that the switches," &c., &c.

The consideration of the voltage in the insulation rules, which we discussed last week, has not been entirely left out of consideration, as Mr. Human suggests in his letter to us on the subject. Nearly half of the rules state that the test is to be made at 100 volts. We have prepared a diagram to illustrate Mr. Human's proposed rules, and have printed it with his letter. The curves are plotted in the same way as our diagram last week, but on a smaller scale. It is noteworthy that the insurance companies have hitherto been content with much lower insulation than the average demanded by supply companies. Mr. Human's proposal, simple and practical as it is, can hardly be said to be the average of modern practice; it appears to be about double. Half the volts divided by the number of lamps, or half the insulation suggested by Mr. Human, may be represented by a curve exactly between curve I and curve T in our diagram on p. 265 of our last issue. Three formulæ may be given for this curve. Half the volts divided by the number of lamps, or 50 megohms divided by the lamps, or, $\frac{1}{10500000}$th part of the whole current. The last form is convenient enough when only $\frac{1}{5000}$ part is specified, but becomes unwieldly in the present case.

With an enterprise worthy of the position which it holds among London newspapers, the *Pall Mall Gazette* is the first large London daily to put down electric motors for driving its presses. Two 40-H.P. "Manchester" motors have been supplied by Messrs. Mather and Platt. They take their current from the outer conductors of the Charing Cross and Strand Company, at 200 volts. The motors run at 800 revolutions, and the main line of shafting at 175. Want of space prevented direct-driving, and a countershaft running at 300 is therefore used. Jaw clutches allow either or both motors to drive. We had the privilege of seeing the plant started for the fourth edition yesterday afternoon. The ammeters showed no appreciable current when running the shafting on light load. A Hoe double-insetting supplement press, folding, cutting, pasting, and arranging in quires, was started by striking gear, and the ammeters showed about 75 amperes each, the speed of the motors hardly varying at all. The supply company thus improve their day load with but little interference with their lighting.

We publish in another column a Paper read by M. Claude before the Société Internationale des Électriciens, describing some striking results obtainable with alternating current circuits. The object of the writer was to devise some means for diminishing the danger of touching one of a pair of high-potential mains traversed by alternating currents. This danger cannot be got rid of by insulating each main from the earth, since in many cases it is due to the capacity which each main has between it and the ground. But M. Claude shows that, by actually connecting each main to the earth, through a choking coil of *low* resistance, and possessing a suitable amount of self-induction, the mains behave as if there were no capacity effect to earth, and can, under these circumstances, be touched without harm, provided that the mains are not connected to earth through a leak having no appreciable self-induction in it. The mains, in fact, behave like a Leyden

Digitized by Google

jar, which, although very highly charged, may, nevertheless, be touched with impunity, provided it is insulated from earth. It does not, however, seem very probable that high-potential mains will be kept permanently connected to earth through choking coils in the manner suggested. The expense of well-insulated coils of the description needed would be very great if the chance of a breakdown were properly ensured against. Moreover, the result mentioned by the writer, that he has managed, by means of the use of a suitable choking coil, to reduce the condenser current from the mains to earth to only 4 per cent. of its value when no choking coil was used, is one which cannot be attained at all easily in practice.

There have been, so far as we remember, only three attempts to apply simple reciprocating motion, instead of rotary movement round an axis, to the armature of a dynamo. The first of these was the "thunder-pump," a magneto device used for ringing-up in the early days of telegraphy. Perhaps this instrument ought not to be classed as a dynamo, but it was a practical success in its day. As much cannot be said for the Edison tuning-fork dynamo. Electrically, this second attempt was reasonable, but it was mechanically impossible and absurd. The third reciprocating dynamo is that of Nikola Tesla. This was first shown in a lecture delivered by the inventor before the Chicago Congress, and is illustrated and described elsewhere in our present issue. The account, for which we are indebted to the *Electrical Engineer* of New York does not allude to the principal object in view in designing this machine. We understand, from the reports of the lecture, that high frequency was Mr. Tesla's aim. In the *Electrical Engineer* of New York, for August 30, 1893, we find that a mass of about 20lb. was kept in vibration with a stroke of ⅞in. at a frequency of about 80 per second, "but by shortening the stroke the weight could be vibrated many hundred times, and has been in other experiments." This result seems hardly sufficient to justify so complete a departure from ordinary practice, but on looking up the subject we found some more figures in the *Electrical World* of New York, for September 2, 1893. "The piston is operated by compressed air at 60lb. per square inch. . . . The compression reaches as much as 16 tons. . . . The number of oscillations used at the lecture was from 50 to 90 per second, although from 5,000 to 10,000 per second have been obtained, and as many more as desirable"!

"The principle underlying" Mr. Hammond's method of coping with the examination of sixty tenders is set forth in our Correspondence columns for the instruction of those who failed to understand our explanation of it last week. These figures are a mere show, they mean nothing; they have this in common with other "business methods." We defy Mr. Hammond to explain how a credit of £37. 10s. is intelligently arrived at as the value of the credit "for superior accessibility and permanence" of one class of boilers over another. We say this the more of the £1 per sq. in. of bearing surface. The bearing surface of an engine may be sufficient, deficient, or excessive. Engine bearings either give no trouble, or they give trouble. The nuisance, the thoughtlessness, and the danger of permitting an engine to be used of which the bearings are considered to be improperly designed are so great that it is impossible to assign even an approximate money value to the fault; to do so may be a "business method," but it is one which we are glad to think is altogether unknown in engineering. It should be observed that, if Messrs. Yates and Thom had been credited with an excess of exactly 17½ sq. ft. of bearing surface over the 84 sq. in. of Messrs. Davey, Paxman and Co., the value of their engine, £2,520, would have been exactly doubled by the "allowance," calculated on Mr. Hammond's system. Any student at a technical college can give Mr. Hammond reasons for providing something less than 17½ sq. ft. bearing surface. The "volume swept by the pistons per minute," the steam consumption, and the mechanical efficiency, are all parts of one and the same quantity. To separate them in this case is to confuse them. A bonus and fine, included in the specification and decided by steam trial, as in the Admiralty tests, is an excellent system, but calculation from the guaranteed, or in some cases not guaranteed, figures of the makers is useless. The object is confessedly not to alter the actual price, but to show the Newport Corporation "the nature of the choice that lay before them." What if the figures were found after all to be wrong? Mr. Hammond asks if any of our readers "can suggest a sounder method of dealing with such tenders," and says that he would be glad to know of it through our columns. It is really asking a good deal of our readers to expect them to instruct Mr. Hammond in the branch of the profession which he has so recently joined.

With regard to the letter from the Secretary of the Brighton and Hove Company, the names of the makers of the plant of that Company are quite sufficient to attest its value as good machinery, and we had no intention of depreciating it, and regret that the words used have been taken to bear such an interpretation. We referred, of course, to the offer made by the Brighton Corporation, which has been accepted by the Company. This offer, as our readers will remember, was as follows:—The Corporation to purchase the Company's undertaking for the sum of £5,000, one-half of which sum to be paid on September 30, 1894, and the other half to be paid within one month of it being certified to the Corporation that the overhead wires, posts and apparatus belonging to the Company have been removed to the satisfaction of the Borough Surveyor; the Company to continue to supply their own customers until September 30th, bearing all the expense and receiving all the revenue.

Mr. Henniker Heaton, having scored less than nothing by his intrusive importunities respecting colonial postage and telegraphs, is now asserting himself in regions nearer home. He wants to reduce the rate for telegrams between France and England to 1d. per word, or, more correctly, to forestall such reduction and take credit for it if it should occur. His information on this point, however, like much else that he is in the habit of parading with oracular confidence, turns out to have no

foundation. There is no condition attaching to the Anglo-French telegraphic agreement of 1889 that the rates should be revised in 1894. Mr. HEATON argues that, in the event of a revision, 1d. per word would suffice, that being the sum of the inland rates of the two countries. The POSTMASTER-GENERAL declined to see it in that light, remembering probably that France, though one of the nearest, is not the only foreign country with which we are connected by cable, and that international barriers, as well as the cost of cables, count for something in the framing of tariffs. That Jersey benefits by the English inland rate, while France does not, is an anomaly for which Mr. HEATON will find plenty of precedents if he will turn his attention to the rates prevailing between towns on opposite sides of continental frontiers, however near those towns may be.

THE chief alteration in the coloured map which forms the supplement to this issue, as compared with our map of last year, is the extension of the City mains. The Chelsea Company has run down the King's-road, but the London Company has followed it, and is in active competition. The Metropolitan Company and St. Pancras Vestry have thrown out a branch or two, but the additions to the mains have, on the whole, been made by "drawing in" additional conductors rather than by advance into new streets.

Dublin.—The Local Government Board have sanctioned the loan of £24,400 for the extension of the electric lighting system.

Electrical Standardising, Testing, and Training Institution.—Mr. James Swinburne is now giving a course of lectures in "Dynamo and Transformer Construction" to the students of this Institution.

The Srinagar-Gilghit Telegraph Line.—The telegraph line to Gilghit, says the *Indian Engineer*, though not completed on a permanent basis, continues to work satisfactorily in spite of the snowfall on the Kashmir passes.

The Telegraph on the West Coast of Africa.—The telegraph system on the West Coast of Africa is being gradually extended. This week it has been notified that a station has been opened at Lomé, in Logoland (German territory), the place being reached by land line from Accra. The line is to be extended shortly from Lomé to Little Popo.

Lighthouse Communication.—The last of the difficulties which have stood in the way of the completion of the arrangements for the telephonic connection of the Goodwin lightships with the shore are now removed, the Ramsgate Corporation having granted the necessary permission for carrying the wires through to the town post-office. The connection will be direct between the North Sand-head lightship and the Ramsgate post-office.

Cable Interruptions and Repairs:

	Date of Interruption.	Date of Repair.

Bonny-Cameroons	Jan. 15th, 1894	—
Foochow-Shanghai	Jan. 15th, 1894	—

Standardising Electrical Instruments.—We are informed that the Owens College Physical Laboratory is prepared to test a limited number of electrical instruments free of charge. The testing will be carried out with all due precautions by qualified assistants, under the superintendence of the Director of the Physical Laboratory. The electrical standards of the laboratory will be compared from time to time with the standards of the Board of Trade, and every effort will be made to ensure accuracy. All inquiries should be addressed to Professor Arthur Schuster, Owens College, and headed "Physical Laboratory Testing Department."

Electric Traction at Hartlepool.—We understand that a syndicate has been formed which has purchased the Hartlepool tramways for the purposes of equipping them with the overhead system. The promoters appeared before the Works Committee of both West Hartlepool and Hartlepool Corporations on Thursday the 11th inst., and after having explained their intentions, the Committee decided to report in favour of the proposition to the Council. We learn that the system is to be considerably extended.

Premiums and Pupils at the Bristol Municipal Electric Light Station.—The question as to whether the engineer to the Bristol Corporation shall be allowed to employ improvers at the Corporation Electrical Works has at length been determined. There has been considerable contention on the matter, and various proposals have been made from time to time. The arrangement come to is that Mr. Faraday Proctor shall be allowed to take two pupils for a period of two years, at a premium of £100 each. Mr. Proctor's share of the £100 will be £15, and the remainder will be placed to the credit of the city.

Newport.—The Parliamentary Committee of the Newport Corporation met on Tuesday to consider the electric lighting report, which was referred back to them for reconsideration by the Council. There was a large attendance. Mr. Hammond, the consulting electrical engineer, was present. Mr. Crompton was granted an audience with the Committee. The discussion upon the question of the alleged "shelving" of Messrs. Crompton's contract occupied a considerable amount of time, and we understand that the *pros* and *cons* of the case were debated at some length by Messrs. Crompton and Hammond. However, no decision was come to in the matter, the consideration of the question being adjourned.

The Government and the Telephones.—Mr. Provand has set down for next session, notice of motion that a Select Committee be appointed to inquire into and report on the proposed arrangement between the Post Office and the National Telephone Company, and generally on the future policy of the Post Office with reference to the extension of the telephone service. We understand, says the *Pall Mall Gazette*, that although the terms of the agreement between the Post Office and the National Telephone Company have not yet been submitted to Parliament they have been practically settled, subject to ratification by the department after the House of Commons has had the promised opportunity of discussing them.

The Halifax-Bermudas Cable.—Strong pressure, says a *Times* correspondent, is being brought to bear upon the Canadian Government by business men in Canada to induce it to grant the extension of the Halifax-Bermudas cable to Jamaica. The leading shippers have been interviewed on the subject, and they hold the extension of the cable to Jamaica and other islands to be absolutely essential to the development of Canadian trade. Four steamers a month are now running from this port to those islands, but business is very much restricted by the high telegraph rates charged, and by the fact that the daily quotations of prices published in the West Indian newspapers come from New York. The extension of the Bermudas cable would make it possible for the Canadian market prices to be published in the West Indies side by side with the American quotations; and with the advantage of cheaper cable rates Canadian trade would be largely increased.

Proposed Adoption of Electric Traction at Bristol.—The Bristol Tramways Company are seeking powers to extend their line to Kingswood, and to work the section by means of electricity. The Directors have decided upon the overhead trolley system. At their invitation the members and officials of the Kingswood and St. George Local Boards inspected the South Staffordshire system on Friday last. At the inevitable dinner, the Mayor of Walsall, said that their system of electric traction had been eminently satisfactory to the town of Walsall; and he had never heard a single inhabitant say a word against it. The ex-Mayor (Mr. Job Wheway) followed,

Digitized by Google

and said that the steam trams were a very great nuisance, but there had been no cause to regret the introduction of electric traction. On the contrary, the local authorities were very thankful for it, and it had been the means of bringing Walsall a bit to the front. It was quite a pleasure to travel on the electric cars, and they felt proud in Walsall that they were wise enough to adopt the system which the deputation had inspected that day. He was one who originally did not believe in the system of electric traction, and he opposed it because he thought it would be a failure. He looked at the posts on paper and thought what hideous things they would be. But he was prepared that day to say that he was penitent, that he recognised his past sinfulness, and that he recognised the advantages they now enjoyed through the system.

Car Brakes.—The following is from the *Electrical Engineer* of New York:—"The recent animated discussion in our pages on the desirability of some better method of car control has received a noteworthy contribution in an accident that occurred at Troy, N.Y., on December 28th. It appears that a car on the Troy City line got away from the motor man. Brakes were applied, but although the wheels ceased their revolution they skidded and the car went on with increasing momentum. The sand-box was freely used and other sand thrown on the track, but to no avail. There was nothing left for the passengers but to jump out. One lady in doing so broke her leg. The motorman stuck bravely to his post on the car, which, after knocking over a fire alarm pole and breaking off at its base a telephone pole, plunged headlong against a building which it shook violently and with a great noise. The car was smashed to pieces, and the motorman was so badly injured that he may not recover. Had not the car butted the building at the foot of the hill it would have committed suicide in the Hudson just beyond. It would seem that this was a casualty that might have been avoided. It should have been possible to reverse the motor instantly, and run up the hill. This was not done, probably because it could not be done with the brakes jammed. As a rule, the brakes on street cars are none too good; but even when they are at their best such accidents happen. That better, or additional, means of control are needed is obvious."

Electricity and Steam Power in Switzerland.—Our contemporary, the *Engineer*, publishes an extract from a recent report of the United States Consul at Chemnitz, Saxony, which it rightly remarks will be of interest to those engaged in applying the waters of Niagara, &c., to the electrical transmission of power to the United States mills and shops. The following table, published at Chemnitz, shows what 50, 300, and 500 H.P. costs per horse-power per annum in Bohemia, England, Germany, and Switzerland:—

Country.	Up to 50 H.P.	Up to 300 H.P.	Up to 500 H.P.
	£ s. d.	£ s. d.	£ s. d.
Bohemia	5 14 7	3 1 6½	2 14 2½
England	5 1 0¼	2 12 6	2 1 4
Germany	6 1 9	3 4 9	2 16 3½
Switzerland	9 15 3	6 3 5¾	5 6 4½

Compared with the preceding the cost of the same amount of horse-power produced by electricity and transmitted 3⅕ miles by an air line in Switzerland, according to results published in connection with the foregoing table, is:—50 H.P., £6 6s. 10d.; 300 H.P., £3. 10s. 10d.; 500 H.P., £2. 12s. 4d. Adding to this the cost of transmission, the total cost will be:—50 H.P., £12. 0s. 5½d.; 300 H.P., £6. 10s. 4d.; 500 H.P., £5. 6s. 3d. It is only by building a large plant—500 H.P. at the very least—that electricity begins to show any profit that would commend it as a substitute for steam.

Adiathermanous Glass.—In *Dingler's Polytechnisches Journal*, 1893, Vol. 287, numbers 1, 3, and 5, there is an interesting Paper by Mr. Richard Zsigmondy, Vienna, on "Glass Transparent to Light, but Opaque to Heat." What is wanted is an absorption-band in the infra-red part of the spectrum. After a series of experiments with alumina, attention was directed to the use of iron salts. A sheet of glass 0·4in. thick, containing 2·8 per cent. of iron as ferrous chloride, allowed only 4·06 per cent. of radiant heat to pass through, while one containing the same quantity of iron as ferric chloride allowed 11·2 per cent. to pass, thus acting little better than water. Next, samples of glass were prepared, one containing 1 per cent. of iron oxide, the second 2, and the third 4 per cent. All were reduced, as far as possible, so as to bring the iron to the ferrous condition. This appeared to have succeeded in the first of the three. The colour was a faint blue, something like a weak copper oxide blue; the other two were bottle-greenish. It seems, therefore, that pure ferrous silicate, without ferric, gives a very pale, pure colour, different from the ordinary colour produced by iron in glass. The spectrum was not materially affected by this glass in layers 0·32in. thick; the violet was slightly weakened, and there was some absorption in the red, about the Frauenhofer line C, but otherwise the spectrum came through pure and bright. The dark absorption-band produced by this glass was in the invisible heat-region of the spectrum. This glass, in layers 0·332in. thick, allowed only 0·4 per cent. of the heat from a batswing burner, 0·72 per cent. of that from an argand burner, or 0·73 per cent. of that from a lime light, to pass through it; but it let through about 12 per cent. of the heat of sun light, while ordinary glass let through 86 per cent. The new glass can thus be used for lamp shades, &c. Its faint blue tint is not unpleasant; but it ought to be possible to make it colourless.

The Blackfriars Accident.—The inquiry was resumed on Tuesday afternoon, before Mr. A. C. Langham, at Guy's Hospital, as to the death, in September last, of Frederick William Ball, aged 34, who was killed by electricity at the Blackfriars-road sub-station of the London Electric Supply Corporation. The inquiry had been adjourned from October for the attendance of Ernest Meech, who was injured at the time, and was now present, and stated that he was still in the employment of the London Electric Supply Corporation. On September 12th he was at the Blackfriars-road station with Ball. It was Ball's duty to turn off the current about six o'clock each evening, and to obtain a fresh supply from Deptford. It was then witness's work, after the current had been switched off, to "clean down." On the night in question he asked Ball, as usual, if it was safe to begin the work, and received a reply in the affirmative. He began to dust down, and on coming to transformer 42 he caught the terminal between the thumb and finger of the left hand. He was standing on the ground at the time, and fell into the pit in an insensible condition. On recovering consciousness he shook Ball, and, receiving no answer to his questions, he concluded he was dead. He then crawled on his hands and knees to the door. By the Coroner: He had then been a fortnight in the employment of the Corporation, and had only been instructed in his duties by Ball. He quite understood that it was dangerous to go near the transformer when the plug was on. The Coroner: Can you account for Ball telling you it was safe?—Witness: I cannot.—The Coroner: Did you wear boots?—Witness: No; but Ball did. We had no gloves on at the time.—A juryman: Did you know the plug was in the transformer?—No. The Coroner said he thought they could come to no other conclusion than that Ball's death was due to an accident; but in returning their verdict he thought the jury might suggest a remedy which might prevent accidents in the future. He thought that india-rubber gloves might be worn with advantage. He was sorry Major Cardew, of the Board of Trade, had been unable to be present. On the last occasion Major Cardew had suggested to him that when the current was on the electric light should be fixed over the place where the contact was made, so that if the current was on it would be lighted by it, and would be seen by those at work. Major Cardew thought the glass globes ought to be coloured red, so that when the workmen went to dust they would at once see the light. He thought that was a very practical suggestion. The jury returned a verdict of "Accidental death," and added, "We are of opinion that had the men been provided with gloves the danger might have been averted. We also think that the rules and regulations at the station should be printed, and that the second man (Meech) should have been more competent before undertaking the work."

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 136.)

The Factor of Underloading.—This coefficient differs from the factor of idleness in not including any estimate of the time during which the plant is not doing any work. From the definition of this quantity it will be evident that if we multiply this factor into the total horse-power of the station or plant, the product will be equal to the average horse-power below the full horse-power at which the station or plant works during the time over which the coefficient is measured. Thus, if the factor of underloading of a 1,000-H.P. station is found to be 0·3, the average power will be equal to 1,000, less 300 H.P., or 700 H.P.; or, to put the matter in another way, if an engine at this station has a rated power of 100 H.P., and a factor of underloading of 0·2, its load factor will be 0·8, and its equivalent average power will be 80 H.P. This 100-H.P. engine is not more effective than an 80-H.P. engine running at full load for the same total time. Besides the idea of idleness here involved, there is another important idea, namely, the idea for which this coefficient has been specially invented. This is, the idea of efficiency of working at reduced loads. Not only will the 100-H.P. engine do no more work than the 80-H.P. one, while costing more to build, but—and this is the point for inquiry—it may happen that the large underloaded engine will take more energy to do the same amount of useful work as the small fully-loaded one, a point which can only be settled by study of each special type of engine. From an economic point of view this coefficient affects the revenue, not so much on the score of prime cost as on account of working costs; and it will be important to know its relation to the efficiency of the engine as indicating the extent to which the working expenses of the plant may be expected to be modified by any variation of the load diagram, or of the distribution of load among the engines which compose that plant. In regard to the main problem this factor will guide the engineer in deciding upon the size and number of the engines as well as, in certain cases, upon the adoption of some auxiliary engine details.

Character of Power-Station Load Diagrams.—The ideal conditions of a power station with factors of idleness and underloading equal to zero are difficult, if not impossible to obtain. This partly arises from the imperfections of the plant and its management, and partly from the intrinsic character of the load diagram. The imperfections in the construction and management of the plant will make it necessary to have a certain amount of *reserve plant*, or excess of engine power over and above the total possible load. The need for this arises from the liability of any unit of plant to become disabled from failure of any part, and from the necessity for laying up each unit of plant from time to time in order to effect cleaning, overhauling and repairs. In a power station which has to be prepared for rapid and considerable extension of the demand for power, it is also necessary to have a certain amount of reserve plant to meet any increase of demand which may arise. The proportion of this reserve to the total plant will be dealt with in a later section. The second cause of underloading and idleness is the imperfect form of the load diagram. We may consider the two principal cases:—(1) A power station for electric lighting and power supply for private consumers, and (2) a power station for electric traction for railways or tramways. In the former there is a long-period variation, the periodic time being a whole day; and the load suffers few but very large variations during that time. There is also a period of longer variation still, for throughout the year the form of the load diagram changes gradually. In the latter there are a great number of rapid and enormous variations at frequent intervals, which are superposed upon a small and gradual variation from hour to hour as the number of cars or passengers varies. The rapid and large changes in the load on the station are caused by the extra power required in starting a car, in taking it up a steep gradient, and in getting it round a sharp curve. Where a very abnormal rise in power occurs it may be due to two or more cars starting at the same time, or to their starting on a steep up-gradient. Apart from these rapid and almost momentary changes in load, the load is practically constant for many hours together, and is not liable to any sudden or unexpected variation. Where the cars are run to scheduled time, it is easy to pre-determine the character of the load diagram. It is not so easy, however, to pre-determine the character of the diagram for an electric supply station. Here, every indeterminate addition or removal of lamps or motors, by hundreds of consumers using power and light for a hundred purposes, will instantly tell upon the total load on the station, and will modify the diagram; while the incidents of dull weather, fogs, and the variations of season, have also their modifying effects. Still, every neighbourhood has its electro-moral character, as it were—a habit of life which is statistically indicated by the load diagrams throughout the year. Where there are theatres, shops and clubs supplied, the character will differ from where the station supplies only private houses; and, while the country station will have all its lights out long before midnight, the city station will be hard at work into the small hours of the morning. The average character of the load diagram of any proposed station may therefore be inferred, either from the known character of the diagrams of another station in a similar district, or from the ascertained variation of load on the mains of the gas supply. This having been done, all necessary allowances must be made for the limits, above and below this average, within which the diagram may be expected to vary. The average load factor of English electric light stations, over a period of a whole year, is not more than 10 or 12 per cent.; the average for the winter months may rise to 25 or 30 per cent., while the summer months may attain an average of less than 5 per cent. In America, where power stations are as much or more employed during the day in running motors, as during the night in running lamps, a station load factor of as high a figure as 50 or 60 per cent. is not uncommon.

Analysis.—Summarising the foregoing discussion of the chief points presented by the problem of the adaptation of motive power and gearing to electrical machinery, we shall find it convenient to dissect the complete problem into the following parts, which analysis will form the basis of subsequent sections:—

(1) The principles of the various types of motive power.

(2) The characteristics of the forms of energy utilised by each type of motive power.

(3) The structure of the engines and of their accessory parts.

(4) The normal, or full load, functions of the engines, and their details.

(5) The influence of varying conditions of load, &c., upon these functions.

(6) The construction and action of gearing.

(7) The relative merits of various forms of gearing.

(8) The economic aspects of gearing and of non-gearing (direct coupling).

(9) The relative merits of the various systems of motive power and gearing from an economic point of view.

(To be continued.)

THE HOURS OF LIGHTING.

In our last issue we gave a striking example of the complication and disorder which arose when a number of different authorities made independent rules for insulation resistance. To-day we give an instance of one of the most regular laws of nature, and of the wonderful unanimity with which it is voluntarily obeyed by hundreds of different individuals. Nearly ten years ago we published in these columns a diagram from which the time of lighting up at any part of the year might be found. and total number of hours in the year, during which light is needed, under given conditions. The correspondent who furnished this diagram, based it upon information obtained from the South Kensington museum. It appeared to be the custom to turn on the electric light from a quarter of an hour to half

Digitized by Google

an hour before sunset. The time at which the light was turned on, depended on two things, each peculiar to the special case. The one, the nature and amount of light wanted for the place,

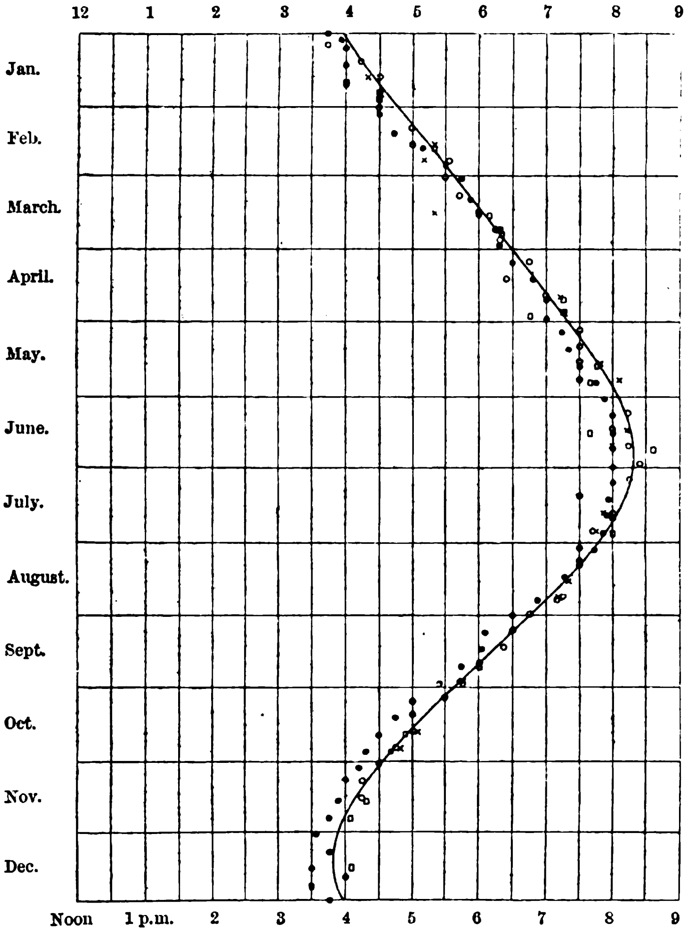

Fig. 1.

Black dots represent	readings	for	1892 St. James and Pall Mall Co.	
Circles	„	„	1893 „	„
Squares	„	„	1892 Westminster Co.	
Crosses	„	„	1893	„

and the other, the judgment of one individual as to the extent to which daylight might diminish before artificial lighting became necessary. The first step towards a more general knowledge of the time during which artificial light is required, is to average a number of different cases, such as shops, private houses, &c., and the next step is to get the opinion of a considerable number of people instead of that of one man. Inspection of the load curve of a supply station enables us to supply both of these needs. It will be remembered that a load curve begins to rise slowly in the afternoon, then more rapidly, as more lights are turned on, and when full load is approached, the rate of increase diminishes, and the curve becomes less steep. The steepest part of the curve evidently extends over that period of time during which the lights are being turned on at the greatest rate. Unless the load curve be of an unusual shape, it may be assumed, without appreciable error, that the middle point of the steepest part is the "average time of lighting up" for that district on that day. We are greatly indebted to the Westminster Electric Supply Corporation and to the St. James and Pall Mall Electric Light

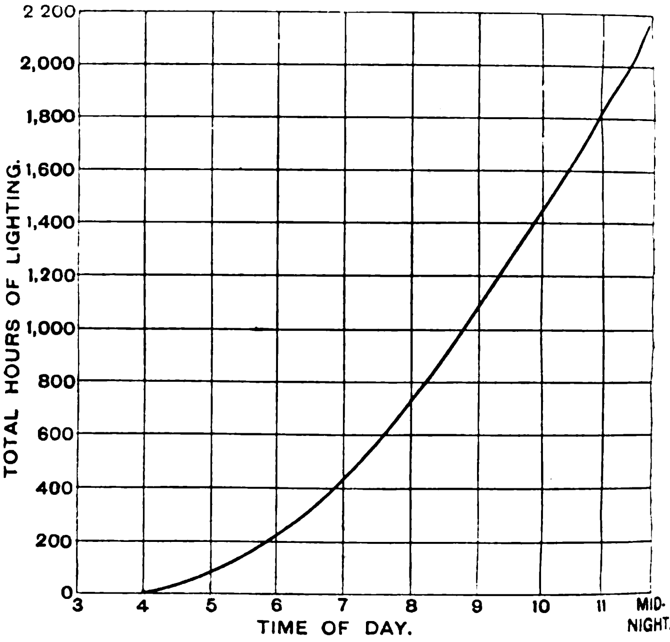

Fig. 3.

Company for the trouble which has been taken at our request to furnish information on this subject. The diagram (Fig. 1) shows a number of points, determined, as we have described, from the middle of the steepest part of the load curves. We expected to find, as in the curve of the Museum lighting, that the average time of lighting up would be a little before sunset, and that the difference would be greater in winter. The curve drawn among the points is the sunset curve, and the uniformity with which the points lie along it is rather striking. Each point is, as it were, the mean result of hundreds of independent voters, each of whom

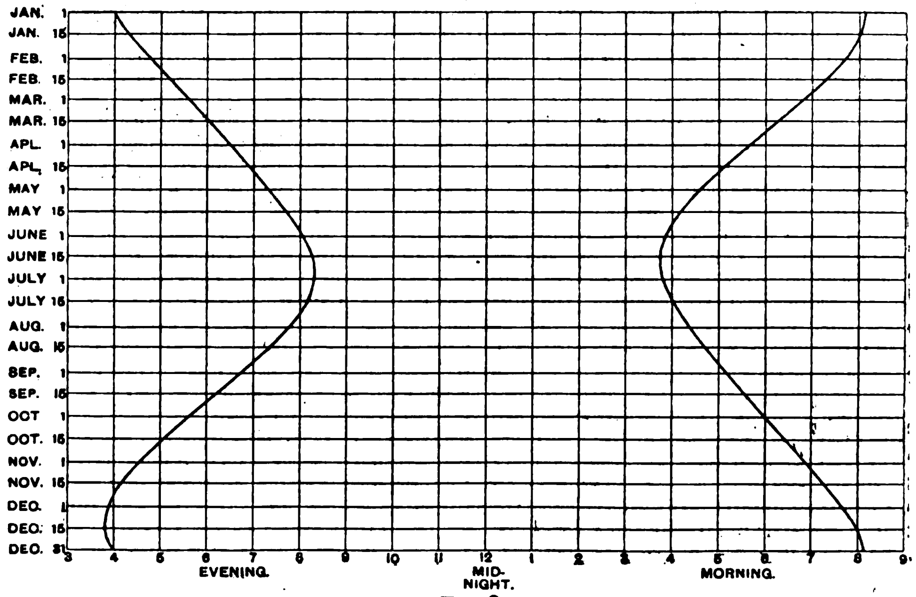

Fig. 2.

in turning on his switch, whether in shops or dwelling-houses, basements or attics, unconsciously influenced the general result. The average time of lighting up seems to be a few minutes before sunset, and the difference in the winter months is only just perceptible. The St. James and Pall Mall Company have sent us some observations for foggy days, but these are hardly sufficient to enable any definite result to be deduced. The curve sent by our correspondent in 1884 was laboriously corrected to include all the fogs during the three years which were averaged. The number and duration of fogs to shift the mean curve a quarter of an hour for, say, two months, would be very considerable, and ought to be averaged over six or eight years.

In estimating the total duration of artificial light throughout a year, under any given conditions, the time of sunset and sunrise may be taken as the average time of lighting up. In Fig. 2 the curves are shown together, as in the diagram published long ago; but they have now been plotted with greater care. The space between the curved lines represents the time during which light is required. The horizontal lines show the months of the year. The vertical lines show the hours. From the sunset curve the curve in Fig. 3 has been calculated. This curve shows the total hours of lighting in a year, from dusk to any given time, and from this curve the following table has been compiled :—

Table showing Hours of Lighting.

Hours of Lighting.	Period of the year during which light is required at these hours.	Total number of hours of lighting per annum.

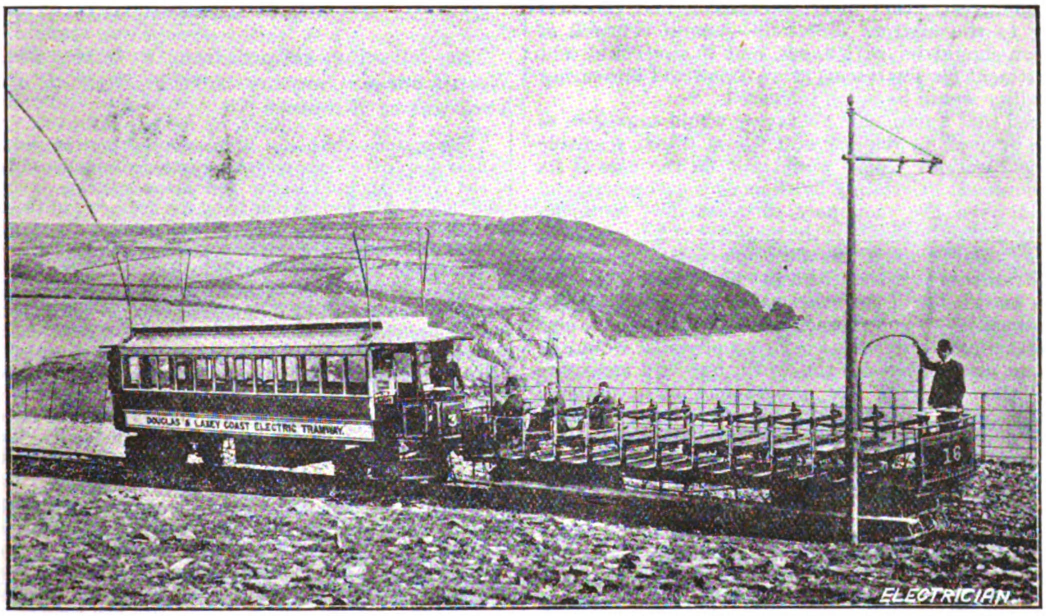
THE DOUGLAS-LAXEY ELECTRIC TRAMWAY.

The accompanying illustration is a view of a section of the Douglas-Grondle Glen Electric Tramway, which was opened to the public last season, and will, it is hoped, be extended, with double track throughout, before next summer to Laxey, a distance of seven miles from Douglas. The electrical plant of the line has been designed by Dr. E. Hopkinson, of Messrs. Mather and Platt, who are the contractors for the machinery and rolling stock. The bridges, earthworks, and embankments (including some heavy sea-works) are being executed by the promoters of the line, to whom Mr. F. Saunderson, of Douglas, Isle of Man, is engineer.



Motor Car and "Trailer" on the Douglas-Laxey Electric Tramway.

The Douglas-Grondle Glen section is 2⅓ miles long, with 5 per cent. and 2 per cent. gradients, no part of the line being level. As will be seen from the illustration, there are two collecting bars on each motor car, which run along the underside of the overhead conductors. These bars are 26ft. apart, so that when passing a pole one bar is always in touch with the overhead conductors.

NATIONAL LABORATORIES.*

BY CH. ED. GUILLEAUME.

If industry owes its immense development in some measure to the application on a large scale of scientific methods, science, on the other hand, could with advantage assimilate industrial methods, by which I mean not merely make use of the material means with which modern industry has endowed the investigator, but rather imitating the organisation and economy of industry. I am speaking of the future, since although this path has been taken it cannot be denied that the greater part of the work remains to be done.

* From *L'Industrie Électrique.*

The tools of the scientist, and more especially of the physicist, are becoming more and more expensive. Experiments are now-a-days carried out on a large scale, and require complicated apparatus. Measurements of precision, researches on high pressures, the obtaining of very low or of very high temperatures, demand very diverse apparatus, each in its way imposing; and a university laboratory, the funds of which are never too plentiful, has either to limit its work to a special line of research or to give up altogether that research work which has made us penetrate so far into the secrets of nature.

Digitized by Google

In many cases the work of a laboratory is decided beforehand; military establishments, for instance, have a very definite object, and a sphere of research which is clearly limited. In others, by choice or by necessity, a single question is attacked, and the physical specialist is created; a profession which is not as yet to be found in any directory, and is, up to the present, but very little understood by the public. No one contests the utility of an astronomer; his science, the most ancient of all, is for many wrapped in a veil of mystery which they are not so indiscreet as to lift. The chemist, even, is no longer questioned; people understand, or think they understand, why it is a man puts on a blouse and heats crucibles, for chemistry has given us a number of products of which no one is ignorant; moreover, a big fortune can be made that way sometimes, which in itself is an irrefutable argument of the utility of chemistry. On the other hand, however, it is difficult to conceive why a sensible man should devote himself to physical research, unless he be a professor or an acquaintance of Robert Houdin. I will not so far insult my readers as to break a lance on behalf of the professional physicist, and will only assert that by the force of things he is every day being brought into existence.

The necessity for concentration of apparatus, for directing scattered effort upon a single well-defined point, and, above all, for filling up the lacunæ of physical science, has brought the question of national laboratories to the front at the same time in several different places. The matter is being considered in England. The influential British Association discusses the proposal at every meeting. In Germany such a laboratory is an accomplished fact: the Reichsanstalt at Charlottenburg, Physico-Technical Institute of the German Empire, presided over by Von Helmholtz, is a national laboratory that has already rendered services, and will, before long, be of priceless value to science and to German industry.

The advantage of a national laboratory is easily understood the moment one thinks of the kind of work it could perform. First of all, it should be the custodian of standards of all sorts, and as such it should be in possession of the best possible appliances for comparing them, a trained staff being specially charged with this work, and with the investigation of all theoretical and practical questions relating to the matter. Secondly, general research of the utmost precision should be carried out, and if one could add an industrial department for the testing of materials and measuring instruments, its utility would be much increased.

It might be feared that a national laboratory would aggregate to itself all the funds devoted to science, and would injure scientific work by over-concentration. Such would not be the case if its object be well understood. Certainly by their very nature national laboratories would have the monopoly of researches requiring apparatus too costly and too special for the majority of laboratories; but, before all, they would come to the aid of physicists by supplying them with instruments to assist them in their researches. At a given moment a knowledge of the exact value of a physical constant becomes a necessity. Who will undertake the long and tedious work which its determination demands? Every physicist would be glad to see someone else undertake the work, but let a managing committee insert the work in the programme of a national laboratory, and the work will be carried out. In university laboratories people could carry out investigations after their own heart without any constraint; whilst at the national laboratory part of the work would be carried out to order and in accordance with an annual programme.

A few instances will show the advantages of such an organisation. When, in view of the 1884 Electrical Conference, people set to work on all sides to determine the value of the true ohm, some physicists constructed everything connected with their mercury standards of resistance, whilst others procured commercial standards of which the makers guaranteed the value. On the one hand there was great labour, and on the other an enormous uncertainty, as was evidenced by the results which the members of the Conference brought together from all countries. The construction and accurate determination of a mercury copy does not demand one twentieth of the work involved in the construction of a primary standard. A central laboratory would have made the latter, and would have distributed exact copies. The work would thus have been greatly diminished, and we should have arrived at the truth far more rapidly. In this way a national laboratory would in no way have interfered with the work; on the contrary, it would have greatly assisted it.

The same would be the case whenever a physicist required an auxiliary instrument in a research, the national laboratory would lend him an electrodynamometer, a resistance box, a thermometer, a divided rule, or a set of weights. The efficiency of scientific workers would in this way be greatly increased, and even the funds of university laboratories would be virtually augmented, since on payment of a reasonable sum they could dispense with the purchase of costly standard apparatus and need no longer pass months in masstering their use. In another direction it may be said that precise determinations of the mechanical equivalent of heat have no meaning so long as we do not define the thermometric scale employed, the numerical value of the intensity of gravity, and lastly, the normal temperature at which we consider the specific heat of water to be equal to unity. Up to the present no physicist who has undertaken this determination has first of all exhaustively investigated these three factors. Thermometry has been the object of special work, the measurement of g has been confided to geodetic establishments for the most part military, finally the specific heat of water has cost MM. Bartoli and Staciati nine years' work. To-day we are fairly clear on this point, but a national laboratory would have done it all for us much more quickly.

In a national laboratory part of the work could be done by a subordinate staff carefully recruited, and finding in their position advantages similar to those offered by commerce, industry, or any other State employment. The practical work of these labourers of science is often very skilled and better than that of scientists themselves, and in any case the work would be done with less waste.

The elements of a national laboratory exist in many countries. In the case of France we need only mention an important department of the Conservatoire des Arts et Métiers, if not the entire establishment; the Laboratoire Central d'Électricité, the Bureau des Alcoolmètres, and other institutions, which would all gain by being united under one management. Certain branches would have to be developed, such as the mechanical laboratory so loudly called for by engineers. The whole should be granted ample funds and given a good staff, and in the end I have no doubt it would be found economical. The realisation of such a scheme would certainly encounter great difficulties. But if we set aside personal questions, delicate matters in every country, must we not admit that in no country would the establishment of a national laboratory be so easy as in France.

THE WESTINGHOUSE PLANS FOR THE NIAGARA CONTRACT.

The following extract from a letter addressed by the Westinghouse Company to the *Electrical Engineer* of New York will be of interest:—

"The system which has been adopted for the installation at Niagara Falls is simply the Tesla polyphase system as developed by the technical staff of the Westinghouse Electric and Manufacturing Company. It has not been modified in any particular by the engineers of the Cataract Construction Company or of the Niagara Falls Power Company. It is fully described in publications of this company and was demonstrated on a large scale by one of our exhibits in the Electricity Building at the recent Columbian Exposition in Chicago. In developing and perfecting the system, we have not only been guided by a wide experience in the design, manufacture and use of electrical machinery, but we have carried out a large amount of experimental work, much of it on an extensive scale, and have made a careful, theoretical and practical study of the subject. Prof. Forbes' views, as stated in his paper, are naturally in accord with ours upon many points. In others, his paper fails to fully state the facts as we see them, and, in others still, we think his views are incorrect. We cannot, therefore, in justice to our company, consent to the assumption that his paper be accepted as a 'fair representation' of our views.

"Some of the technical journals have apparently received the impression that the generator described in Prof. Forbes' paper under the heading 'General Description of a 5000-H.P. Alternator' is that which has been adopted by the Cataract Construction Company. This is not the case. The drawings and specifications of the generator, which Prof. Forbes describes, were laid before us in August last, and were fully explained by Dr. Coleman Sellars and Prof. Forbes. After careful consideration, we accepted the general mechanical features of the construction proposed as excellent, but, in the opinion of our electricians and engineers, the electrical features—the method of winding, the insulation, etc.—were impracticable, and realising that we could not undertake the construction of such a machine with credit to our Company, we declined to submit proposals. We were thereupon requested by the officers of the Cataract Construction Company to submit our own plans and specifications, and this was done early in August. We followed closely the mechanical features approved by Dr. Sellars, but the electrical features are wholly our own. These plans were accepted by the Cataract Construction Company and are those under which the generators for Niagara are now being constructed.

"Prof. Forbes is undoubtedly qualified to speak with authority as to the assumptions and reasoning which have led him to agree with other engineers of the Cataract Construction Company in recommending to his Board of Directors the adoption of the system which has been selected, but the premises and the reasoning which guided the engineers of the Westinghouse Electric and Manufacturing Company in the development of the Tesla polyphase system, as it will be used at Niagara, differ widely in some respects from those which are set forth in the paper to which your editorial refers.

"We trust that you will give to this explanation suitable prominence, as we are unwilling, for the reasons stated, to have Prof. Forbes' paper accepted by your readers as a statement of our views."

NOTE ON GUTTA-PERCHA.*

BY J. LAGARDE.

I have lately been able to procure a sample of copper covered with gutta-percha extracted from the leaves of the isonandra by M. Serulla's process. The insulation seemed very high, but I was unable to measure it, the length of the sample being only 1 metre; I was therefore obliged to confine myself to analysing the gutta-percha, the analysis giving the following results :—

Water	Nil.
Impurities	0·8 per cent.
Resins	16·0 " "
Gutta-percha	83·2 " "
	100·0 per cent.

I separated out the resins and found them to be as below :—

Fluavil	1·72 per cent.
Alban	14·28 " "
	16·00 per cent.

The large amount of alban as compared with fluavil, and especially the absence of water, are sufficient to account for the high specific insulation attributed to this dielectric, notwithstanding the large proportion of pure gutta. I am, moreover, inclined to think that by reason of the absence of water this gutta-percha will oxidise less easily than those brands which have hitherto been used, and consequently that it will last longer.

As the facilities that have been afforded me for investigating the properties of gutta-percha are about to fail me I am, to my great regret, obliged to relinquish the study of this question as well as that of many matters affecting telegraphy. Nevertheless what I have published on this subject seems to me sufficient to show what are the effects of water and resins on gutta-percha. Water diminishes its insulating power, and facilitates its oxidation; the resins, especially alban, increase its insulating power, but, at the same time, are a source of deterioration. Two submarine or subterranean cables, covered with very different gutta-perchas, may, at a given moment, show the same insulation; but that, the gutta-percha of which contains less water and resin, will remain sound for the longer time. Analysis, therefore, presents itself as the only means of discovering whether the gutta-percha on a cable is of good or bad quality, and it is because analyses were not carried out a few years ago, that is to say, previous to my investigations, that some submarine and subterranean cables of bad quality were accepted, which, nevertheless, fulfilled the specified electrical conditions. The cores of the submarine cables deteriorated so much after a few months' sojourn under water that it was impossible to use them. As to the subterranean cables, the insulation of several lengths appreciably decreased before they were put into use, and some could not even be employed at all. Moreover, at the time when the interurban underground network was being laid down, it sometimes happened that on soldering up two cable ends in somewhat cold weather the gutta-percha cracked. This must have been caused by the large quantity of alban contained by the gutta-percha, and not as I suggested when consulted at the time.

It would be a useful termination to my investigations on gutta-percha if I could answer the following question :—Has pure gutta-percha coming from different sources identical electrical qualities? To solve this question it would seem a natural thing to do to cover copper wires of the same diameter with the same thickness of dielectric, and then to measure the insulation and capacity. But to do this it would be necessary to raise the gutta-percha to a somewhat high temperature at which it might oxidise. So that it would seem to me better to reduce the gutta-percha to very fine sheets of the same thickness, and to make condensers instead of cores, and I employed this method some little time ago when testing two samples of pure gutta-percha, one of which came from a very good and the other from a very bad source; I was not, however, able to obtain any results owing to the small amounts of gutta-percha at my disposal, and the test must be renewed. The numerous experiments that I have carried out, only a few of which have been published in the *Annales Télégraphiques*, had to do with gutta-percha of all kinds coming from seven different factories. The results were always similar, which leads me to believe that the various pure gutta-perchas the samples contained had the same electrical qualities. I cannot, however, assert this. If, on the other hand, this is not the case, my conclusions as to the influence of water and the resins, and as to the necessity of determining the amounts of these substances that are contained in the gutta-percha of a cable, would in no way be affected; indeed, analysis would be all the more necessary, since electrical tests would tell us less about the value of the gutta-percha employed than they would if all kinds of pure gutta-percha possessed the same qualities.

In conclusion, I will repeat that I consider tolerably good gutta-percha to be that which contains at least 55 per cent. of pure gutta, and at the most 5 per cent. of water and 1 per cent. of foreign substances, and in which the amounts of alban and fluavil are equal. Good gutta-percha should contain at least 60 per cent. of pure gutta, and at the most 5 per cent. of water and 0·8 per cent. of foreign substances, the amounts of alban and fluavil being equal. Finally, gutta-percha of very good quality should contain at least 65 per cent. of pure gutta, and not more than 3 per cent. of water, 0·5 per cent. of foreign substances, and 12 per cent. of alban.

* From the *Annales Télégraphiques*, Vol. XX.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, January 19th.

INSTITUTION OF CIVIL ENGINEERS.

7 30 p.m. Students' Meeting at 25, Gt. George-street, S.W. The following Paper will be read: "Discharging and Storing Grain," by Mr. William G. Wales, Stud.Inst. E.C.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street, S.W. The following Paper will be read: "Multiphase Currents and their Applications," by C. V. Drysdale, Student.

SATURDAY, January 20th.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Visit to the Engineering Laboratories and Workshops of the Battersea Polytechnic Institute, Battersea Park-road, S.W.

MONDAY, January 22nd.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. "The Detection and Measurement of Inflammable Gas and Vapour in the Air," by Frank Clowes, D.Sc.

TUESDAY, January 23rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Locomotion and Fixation in Plants and Animals," by Prof. Charles Stewart, M.R.C.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. The following Paper will be read: "The Tunnels of the Dore and Chinley Railway," by the late Percy Rickard, M.Inst.C.E.

WEDNESDAY, January 24th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "American Carriages," by G. Herbert Thrupp.

THURSDAY, January 25th.

INSTITUTION OF CIVIL ENGINEERS.

2 45 p.m. Students' Visit to the Cable Depot of the London Tramways Company, Streatham Hill.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. The following Paper will be read: "Notes of a Trip to the United States, and to Chicago, 1893," by W. H. Preece, C.B. F.R.S., Past President.

FRIDAY, January 26th.

PHYSICAL SOCIETY.

8 p.m. The following Papers are down to be read: (1) "A New Mode of Making Magic Mirrors," by J. W. Kearten. (2) "Some Observations in Diffraction," by W. B. Croft, M.A. (3) "A New Photometric Method and Photometer," by J. W. Spurge.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at the St. James's Hall Restaurant (Banquet Room), Regent-street, W.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse: "Old Irish Song" (with vocal illustrations by Mrs. Hutchinson and Madame Marie Brema), by Alfred Perceval Graves, M.A.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Royal Society.—The following Papers were down for reading yesterday :—E. H. Griffiths, "Appendix to a communication termed 'The Mechanical Equivalent of Heat.'" O. Heaviside, "On the Transformation of Optical Wave-surfaces by Homogeneous Strain." G. A. Schott, "On the Reflection and Refraction of Light."

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 8s. 6d. net, post free, 9s., abroad, 9s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

SPECIAL NOTICES.

We publish this week (Gratis to Subscribers) a COLOURED MAP, showing the Streets in the Metropolis in which Mains for Private Lighting are actually laid, up to January, 1894, with the areas allotted to the different Supply Companies.

With the issue of "The Electrician" for January 26th will be published (Gratis to Subscribers) a fine STEEL-PLATE PORTRAIT of Mr. ALEXANDER SIEMENS, President of the Institution of Electrical Engineers for 1894.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; and Joseph Wilson Swan, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

MR. ALEXANDER SIEMENS' PRESIDENTIAL ADDRESS.

Presidential addresses before scientific societies often consist of elaborate Papers by specialists on their own subjects, Papers which might have been contributed to the societies in the usual way, but upon which unusual care has been expended; or they present a historical record of the past ten, fifty, or hundred years. Too seldom do presidents offer in their addresses original thoughts on general subjects, and examine the causes and conditions which have determined the growth of a science or the development of an industry, the circumstances which are influencing its present position, and the factors which may affect its future. Important though it was as a special contribution to our knowledge, the address, for example, by Dr. J. HOPKINSON on Magnetism may be classed with the other valuable writings of the same author. Historical and statistical addresses ought to be useful historically and statistically—they seem to be

so, while they are being delivered; but who ever consults them afterwards when searching for historical or statistical information? Any specialist can write a Paper on his own subject, and he may mark the occasion by publishing some new research for the first time. Not even personal work is needed for the review-of-a-century address, and it is difficult to infuse the personality of the author into it. The Presidential address of Mr. SIEMENS, half of which we print elsewhere, is of the rarer kind to which we have alluded. It deals with many subjects which are seldom brought before the meetings of the Institution of Electrical Engineers, and is well worthy of thoughtful study.

Mr. SIEMENS begins with a clear account of the electric lighting legislation which has starved that which it was intended to foster, and has impeded that which it was meant to encourage. The curious changes in this legislation, and its influence on the progress of electrical engineering, are briefly discussed, and in concluding this part of his address the President clearly points out the principal cause of the delay in the development of electric supply. It is true that the 21 years' purchase was a mistake; it was intended to encourage municipalisation, but it only checked, perhaps wholesomely checked, an industry which was destined without any State encouragement to fall into the hands of municipal authorities. It is true that the system of licences, which might have allowed this country to enjoy the facilities under which supply systems have developed in other lands, has been dropped, and that the consent of the local authority is absolutely necessary; all these hindrances have had their effect. But the principal cause of the delay has been "the exaggerated expectations that were raised either by ignorance or by design, when the general public first seriously thought of regarding electricity as a commodity for every day use. . . . There was a short time of excitement to the public and of profit to the promoters; then the confidence of the public in electricity was almost destroyed, and could only be repaired by years of patient work." Nothing but the payment of dividends could restore this confidence. The display of actual electric lighting by pioneer stations was of no more value than the promises of the pioneers, of whom Mr. SIEMENS speaks moderately. But no sooner were a few sound systems established—at the cost of immense exertion and enterprise, both of capitalists and of engineers, and dividends paid—than the municipal authorities at once seized upon the industry; dividends will no longer be the measure of success, but those obscure "profits" which, as the President says, have already "relieved the rates at the expense of the wealthier classes, in a perfectly legitimate manner."

Passing on to emphasise the importance, nay, the absolute necessity, of sound mechanical engineering, he alludes to the electrical appliances, which were formerly constructed like scientific instruments, with a neglect of mechanical considerations, and to the healthy re-action which took place, but which, indeed, is not yet complete, when the mechanical engineer took over the applications of electrical energy from the hands of the instrument maker. He brings back enthusiastic schemes for traction at 200 miles an hour, and the nine days' wonder of the Frankfort-Lauffen transmission, to the sound standpoint of concerns which will pay.

With Mr. SIEMENS' opinions on the education of engineers we cordially agree, coinciding so completely as they do with the views often put forward in these columns, and offering so salutary a protest against the system advocated by many teachers. The distinction between education and instruction, for which we have combated, is thus clearly expressed:—"It has always appeared to me that at school the mental powers should be principally exercised in a way to make them fit for learning. . . . Although it has been the fashion of late to deprecate the study of Latin and Greek, I am quite certain that the attack is made from quarters where the mental training which the study of these languages entails is not appreciated at its right value, nor is the enormous advantage considered which their knowledge gives in the study of modern languages. After the mental powers have been prepared in this way, it is of no great consequence whether most of the details of the school teaching are speedily forgotten or not; the essential point is that the student should have acquired a good method of learning, so as to assimilate to the best advantage the course of training he attends at college." We commend these views to those who ridicule the acquisition of "useless knowledge." The President advocates, as we have done, that "the teaching at engineering colleges should be confined to general principles," and he deprecates the tendency which is present even at the older Universities towards early specialisation, by pointing out that "while the student is trained afterwards in practical work, he has time to select to what special branch of the profession he wishes to devote his life." We welcome this part of Mr. SIEMENS' Presidential Address the more since it comes from one who must be familiar with the elaborate system of so-called technical education on the Continent, which we are continually informed is so much better as an educational instrument than anything we have in this country.

THE TESLA ELECTRICAL OSCILLATOR.*

In the lecture delivered before the Chicago Electrical Congress, Mr. Nikola Tesla first drew attention to the method which he had devised for the continuous production of alternating currents of constant period by the employment of his oscillating engine, in which all rotating parts are avoided directly to the movement of the generating coil in the magnetic field. In applying the Tesla oscillator for the generation of currents of constant period certain conditions are encountered which must be taken into consideration in order to satisfactorily secure the desired result. These conditions may be secured by properly proportioning the self-induction and capacity of the circuit, including the generator.

Mr. Tesla has, however, observed the further fact in connection with the use of such engines as a means for running a generator, that it is advantageous that the period of the engine and the natural period of electrical vibration of the generator should be the same, as in such case the best conditions for electrical resonance are established, and the possibility of disturbing the period of mechanical vibrations is reduced to a minimum. Mr. Tesla has found that even if the theoretical conditions necessary for maintaining a constant period in the engine itself are not exactly maintained, still the engine and generator combined will vibrate at a constant period. For example, if instead of using in the engine an independent cylinder and plunger, as an airspring of practical constant rigidity, the piston may impinge upon air cushions at the ends of its own cylinder. Although the rigidity of such cushions or springs might be considerably affected and varied by the variations of pressure within the cylinder, still, by combining with such an engine a generator which has a period of its own, approximately that of the engine, constant vibration may be maintained even through a considerable range of varying pressure, owing to the controlling action of the electromagnetic system. Under certain conditions the influence of the electromagnetic system may be made so great as to entirely control the period of the mechanical vibration within wide limits of varying pressure. This is likely to occur in those instances where the power of the engine, while fully capable of maintaining a vibration once started, is not sufficient to change its rate.

Referring to Fig. 1, A is the main cylinder in which works a piston, B. Inlet ports, C C, pass through the sides of the cylinder opening at the middle and on opposite sides. Exhaust ports, D D, extend through the walls of the cylinder and are formed with branches that open into the interior of the cylinder on each side of the inlet ports and on opposite sides of the cylinder. The piston, B, has two circumferential grooves, E F, which communicate through

* Abstract from an advance proof, kindly sent by the *Electrical Engineer* of New York.

Digitized by Google

openings, G, in the piston with the cylinder on opposite sides of the piston respectively.

The particular construction of the cylinder, the piston and the ports controlling it, may be very much varied, and is not in itself material, except that in the special case under consideration it is desirable that all the ports, and more especially the exhaust ports, should be made very much larger than is usually the case so that no force due to the action of the steam or compressed air will tend to retard or affect the return of the piston in either direction.

The piston, B, is secured to a piston rod, H, which works in suitable stuffing boxes in the heads of the cylinder, A. This rod is prolonged on one side and extends through bearings V in a cylinder, I, mounted in line with the first, and within which is a disc or plunger, J, carried by the rod H. The cylinder I is without parts of any kind and is air-tight, except as a small leakage may occur through the bearings V, which experience has shown need not be fitted with any very considerable accuracy.

The cylinder I is surrounded by a jacket, K, which leaves an open space or chamber around it. The bearings V in the cylinder extend through the jacket to the outside air, and the chamber between the cylinder and the jacket is made steam or air-tight by a suitable packing. The main supply pipe L, for steam or compressed air, leads into this chamber, and the two pipes that lead to cylinder A run from this chamber, oil cups M being conveniently arranged to deliver oil into the pipes for lubricating the piston.

In the particular form of engine shown, the jacket K, which contains the cylinder I is provided with a flange N, by which it is screwed to the end of the cylinder A. A small chamber O is thus formed, which has air vents, P, in its sides, and drip pipes Q leading out from it through which the oil which collects in it is carried off.

In the position of the parts shown, or when the piston is at the middle point of its stroke, the plunger J is at the centre of the cylinder I, and the air on both sides of the same is at the normal pressure of the outside atmosphere. If a source of steam or compressed air be then connected to the inlet ports C C of the cylinder A, and a movement be imparted to the piston as by a sudden blow, the latter begins to reciprocate in the well-known way.

The movements of the piston compress and rarefy the air in the cylinder I at opposite ends alternately. A forward stroke compresses the air ahead of the plunger J, which acts as a spring to return it; similarly, on the back stroke the air is compressed on the opposite side of the plunger J, and tends to drive it forward.

The compressions of the air in the cylinder I, and the consequent loss of energy due mainly to the imperfect elasticity of the air, give rise to a very considerable amount of heat. This heat is utilised by conducting the steam or compressed air to the engine cylinder through the chamber formed by the jacket surrounding the air-spring cylinder, the heat thus taken up and used to raise the temperature of the steam or air acting upon the piston is availed of to increase the efficiency of the engine.

In any given engine of this kind the normal pressure will produce a stroke of determined length, and this will be increased or diminished according to the increase of pressure above, or the reduction of pressure below, the normal. In constructing the apparatus proper allowance is made for a variation in the length of stroke by giving to the confining cylinder I of the air spring properly determined dimensions. The greater the pressure upon the piston the higher will be the degree of compression of the air spring, and the consequent counteracting force upon the plunger.

The rate or period of reciprocation of the piston, however, is mainly determined by the rigidity of the air spring and the inertia of the moving system, and any period of oscillation within very wide limits may be secured by properly portioning these factors, as by varying the dimensions of the air chamber, which is equivalent to varying the rigidity of the spring, or by adjusting the weight of the moving parts. These conditions are all readily determinable, and an engine, constructed as above described, maintains a perfectly uniform period through very wide limits of pressure.

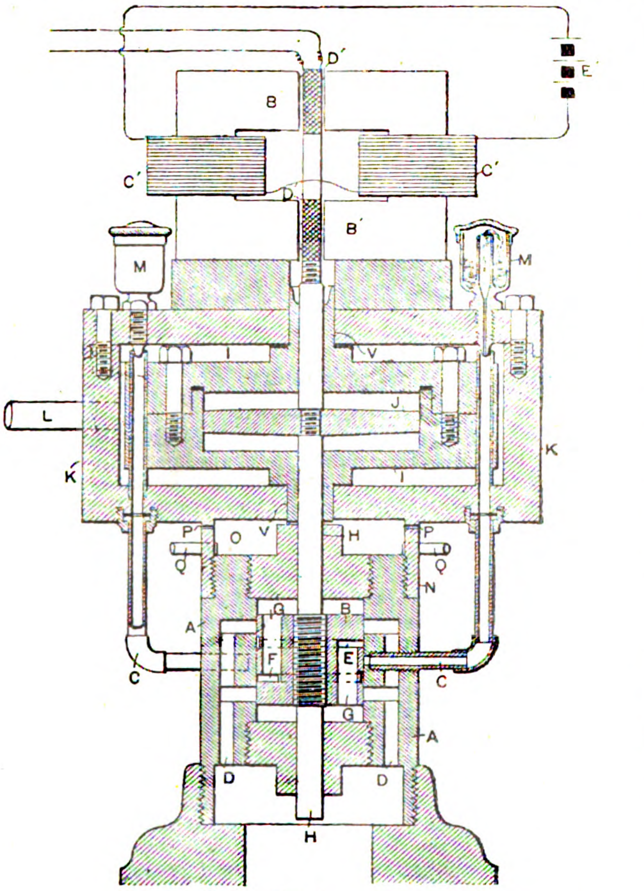

Fig. 1.

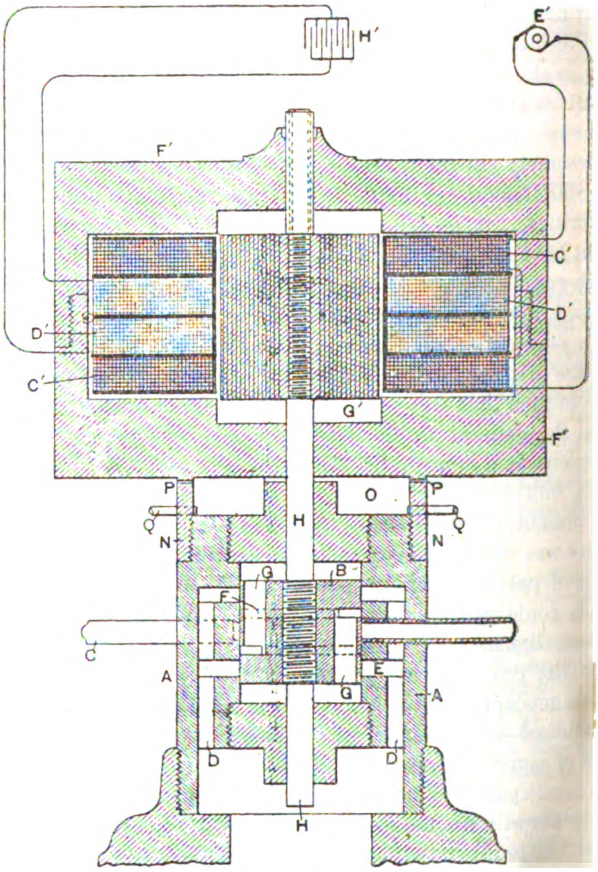

Fig. 2.

To the piston rod H is secured a coil, D′, which, by the movements of the piston, is oscillated in the magnetic field produced by two magnets, B′ B′, which may be permanent magnets or energised by coils, C′ C′, connected with a source of continuous current, E′. The movement of the coil D′ across the lines of force established by the magnets gives rise to alternating currents in the coil. These currents, if the period of mechanical oscillation be constant, will be of constant period.

In the case under consideration it is assumed as a necessary condition that the inertia of the movable element of the generator and the electromagnetic reaction which it exerts will not be of such a character as to materially disturb the action of the engine.

Fig. 2 is an example of a combination in which the engine is not of itself capable of determining entirely the period of oscillation, but in which the generator contributes to this end. In this figure the engine is the same as that shown in Fig. 1. The exterior air spring is, however, omitted, and the air spaces at the ends of the cylinder A relied on for accomplishing the same purpose. As the pressure in these spaces is liable to variations from variations in the steam or gas used in impelling the piston they might affect the period of oscillation, and the conditions are not as stable and cer-

Digitized by Google

tain as in the case of an engine constructed as in Fig. 1. But if the natural period of vibration of the elastic system be made to approximately accord with the average period of the engine such tendencies to variation are very largely overcome, and the engine will preserve its period even through a considerable range of variation of pressure.

The generator in this case is composed of a magnetic casing F′, in which a laminated core G′ secured to the piston rod H is caused to vibrate. Surrounding the plunger are two exciting coils, C′ C′, and one or more induced coils, D′ D′. The coils C′ C′ are connected with a generator of continuous currents, E′, and are wound to produce consequent poles in the core G′. Any movement of the latter will therefore shift the lines of force through coils D′ D′, and produce currents therein.

In the circuit of coils D′ is shown a condenser, H′. By the use of a proper condenser the self-induction of this circuit may be neutralised. Such a circuit will have a certain natural period of vibration, and as this depends upon the capacity and self-induction, the period may be varied to approximately accord with the period of the engine.

In case the power of the engine be comparatively small, as when the pressure is applied through a very small fraction of the total stroke, the electrical vibration will tend to control the period, and it is clear that if the character of such vibration be not very widely different from the average period of vibration of the engine under ordinary working conditions, that such control may be entirely adequate to produce the desired results.

ON THE MEANS OF INCREASING THE SAFETY OF HIGH-PRESSURE ALTERNATE-CURRENT DISTRIBUTIONS.*

BY G. CLAUDE.

One of the most serious defects of the high-pressure alternate current is undoubtedly the danger to human life. An investigation, therefore, into the means by which we can as far as possible increase the safety of alternate currents is of capital importance, and the following ideas on the subject may be of interest to you.

To increase the safety of a given system it would seem at first sight as if the means available were few; that the only thing to be done is to make the insulation of the system as high as possible, taking every imaginable precaution to prevent contact between the human body and any parts at a high potential. If, in practice, too much importance is attached to the first condition, it is impossible to observe the second very thoroughly. It is, in fact, certain that if, by suitable arrangements, we could absolutely prevent contacts between the body and high potentials, the question of the safety of high-pressure distributions would by that very fact be completely solved. Unfortunately in practice this cannot be done, and whatever precautions may be taken, an imprudent act, an accident, may at any moment result in the dreaded contact, involving as a consequence the death of the individual in question.

By quite other methods, however, it is possible to obtain important results. Since we cannot entirely prevent contact, we can at least arrange matters so that in the majority of instances these contacts shall be harmless. This result may appear at first sight rather difficult to obtain, but, as a matter of fact, it is easily reached if we take into consideration an element which up to the present has been somewhat neglected, notwithstanding that it plays the principal part in the majority of accidents, due to the alternate current; this element is the capacity of the system of distribution.

In a general manner the capacity may be divided into (1) the direct capacity, C_1, between the two cables; (2) the capacity, $C\ C'$, of each cable with respect to earth, so that the total capacity, C_2, of the two cables becomes $C_2 = C_1 + C\,C'/(C + C')$. When the current is on, each of the condensers, C_1, C, and C' (Fig. 1) is submitted to an alternating potential, and we know that under these conditions it presents an insulation resistance of the form $1/\omega C_2$; that is to say, the apparent resistance between the two cables is $1/\omega C_1$, and that between each cable and earth is $1/\omega C$ and $1/\omega C'$ respectively. In practice, moreover, the values of C_1, C, C' and ω are such that the corresponding *apparent* resistances $1/\omega C_1$, $1/\omega C$, and $1/\omega C'$ are, at the most, a few thousand ohms, so that we may totally disregard the *ohmic* resistances ρ_1, ρ, and ρ', measured when the line is at rest, which are always of the order of tens of megohms. In other words, the insulation of a given system of distribution, measured during rest, may be excellent, and reach hundreds and even thousands of megohms, but the moment the dynamos are switched on this insulation becomes only *a few thousand ohms*. Thus, on the Halles network I found for each lead an insulation resistance of only 2,000 ohms with the dynamos at work.

* Abstract of a Paper read before the Société Internationale des Électriciens.

It is necessary to distinguish the two capacities, viz., the direct capacity and that between the cables and earth, for, from the point of view I propose to take up, their influence is of very different importance. In fact, however large the direct capacity C_1, and however small in consequence the resistance $1/\omega C_1$, there is no danger; it is in fact as if we united the conductors of the two cables by a metallic resistance, such as the primary of a transformer, of impedance $\sqrt{R^2 + \omega^2 L^2}$ equal to $1/\omega C_1$. But this is not the case with the apparent resistances to earth $1/\omega C$ and $1/\omega C'$, and the low values that these have in practice may have the gravest results as regards human life. There is between each cable and earth a difference of potential which, if we suppose the apparent resistances of the two cables to be equal, is equal to one-half the total difference of potential that is impressed upon the system. If an earthed individual touches *one* pole of the system his body is submitted to this difference of potential, which in the majority of cases is greater than 1,000 volts, and which falls but slightly in consequence of the contact, the apparent resistance of the corresponding cable being small compared with that of the body. The result is a permanent current through the body of sufficient amount, if its application is prolonged, to cause death. This is the way in which the majority of accidents connected with alternate currents arise.

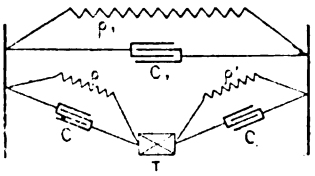

Fig. 1.

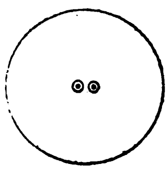

Fig. 2.

If, on the other hand, we are able by any device whatsoever to greatly increase the *apparent* resistance of either cable, the danger of touching *one* pole when to earth would be completely overcome, since the current could not complete the circuit to the other pole through a low apparent resistance. In other words, there would always exist between each cable and earth a difference of potential equal one-half the total, but this difference of potential instead of being *stable* would be *unstable*, and would fall to zero, or at any rate to a very small figure the moment contact was made with the cable. On this hypothesis one must in order to be in danger touch two poles *simultaneously*, an occurrence which is evidently much more infrequent than the coming into contact with a single pole. Hence in this manner the most common cause of accident would be eliminated. Now, since the capacity is the sole cause of the lowness of the apparent resistance the inevitable conclusion is that it would be enough to annul the capacity or to combat its effects.

Here a word of explanation is necessary. Capacity, as M. Boucherot has pointed out, plays a beneficial part in alternate-current distribution, besides having the effects analysed above. Capacity diminishes the lag of transformers during light and no load, and consequent beneficially affects the efficiency, diminishes in a degree that may be considerable the current output of the alternators at these loads, whilst its influence, which is unfavourable at full load,

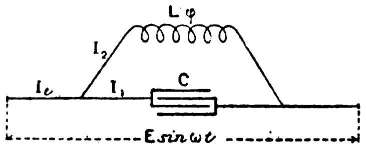

Fig. 3.

is then negligible. In short, the influence of capacity is so advantageous that according to my experience at the Halles the average annual power factor is 0.9, when without the capacity of the cables it would be only 0·82 to 0·83. We can see by these figures what the influence of capacity must be at no load, and especially what it would be if the network were more extensive and the capacity greater.

It would, therefore, be a pity to completely suppress the capacity with a view to securing safety. Fortunately this result need not be feared, since we see, by what has been previously said, that the direct capacity between the cables does not enter into the question of safety, so that we can leave it alone or even try and increase it as much as possible by the employment, for instance, of concentric cables. All we have to eliminate is the capacity with regard to earth, and for that purpose we have three different methods at our disposal.

Firstly, the expression for the apparent resistance being of the form $1/\omega C$, we see for a given network that as regards capacity the smaller ω is the better will be the apparent insulation; a fact which leads us to the use of the lowest possible frequencies. In practice the frequency varies between $\omega = 100$ and $\omega = 500$. From

Digitized by Google

this it follows that according to the frequency adopted the apparent insulation of a network may vary in the ratio of 1 to 5.

Again, we may go to work on the earth capacity itself, and by suitable dispositions bring this capacity down to as low a figure as possible. In this way we could obtain appreciable results if we placed our cables in the middle of large diameter tubes (Fig. 2), and all the more so because the dielectric constant of air is only one third or one quarter of that of the ordinary cable insulation. In this connection it may be worth while to mention overhead cables which, having a very small capacity with regard to earth, have, even when insulated with corresponding care, an apparent insulation far greater than that of underground cables.

But it is clear that we are not in a position to make use of the two devices I have just pointed out in the case of an existing installation.

My last suggestion is to neutralise the effects of earth capacity by making use of the well-known properties of self-induction. In order to ascertain how far it is satisfactory we must solve the following

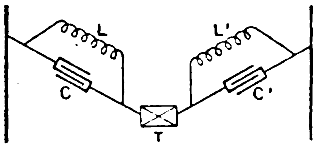

Fig. 4.

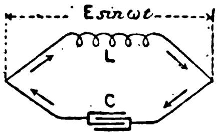

Fig. 5

problem. The apparent resistance of a capacity C being $1/\omega C$, what does it become when we shunt that capacity by a self-induction as in Fig. 3 the final result is

$$I_t \min = E \, \omega \, C \cos \phi \, (\omega \, t - \phi_1)$$

where I_t is the total current, and $E \sin \omega t$ is the difference of potential.

We thus see that by the addition of the self-induction placed in shunt with C we are able to substitute for the original apparent resistance $1/\omega C$ a new apparent resistance $1/\omega C \cos \phi$, which is always larger, and in this way obtain the arrangement shown in Fig. 4. The ideal would be to obtain an infinite insulation, but to do so $\cos \phi$ must equal zero, hence $\phi = 90°$, which is not practically realisable, since self-inductions are not perfect and never have zero ohmic resistance. If the inductance we make use of is the primary of a closed magnetic circuit transformer we know that at no load $\cos \phi$ is never less than 0·5 or 0·6, so that all we can do is to double the apparent resistance. This is, in fact, the experimental result that I have obtained on the Halles network with Ferranti transformers. If the efficacy of the device were limited to this it is certain that its application would not be very useful. But if we employ suitable impedance coils we can make $\cos \phi = 0{\cdot}04$, or even less, so that it is possible to make the apparent insulation resistance *twenty-five times greater*. This result is of supreme importance. The apparent resistance so obtained being much greater than that of the human body, a contact between it and one of the cables will make the difference of potential between the cable and earth fall to a very small value. We therefore arrive at this conclusion, which at first sight appears very singular, namely, that the most efficacious method of improving the working insulation of a network is to metallically connect each cable to earth by resistances of fairly high apparent resistance, but of very small ohmic resistance.

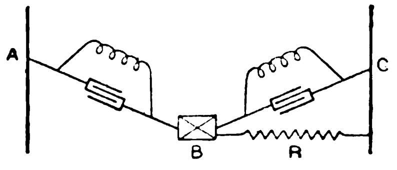

Fig. 6.

The physical explanation of this result is very simple. Owing to the lead caused in the capacity, and the lag caused in the inductance, and to the relationship between capacity and inductance, which in the case of a perfect arrangement would be $\omega^2 L C = 1$, the two branches, L and C (Fig. 5), are traversed at any instant by equal and opposite currents whatever may be the difference of potential, E, at their terminals. The system acts, therefore, as a closed circuit, into which no outside current can enter. If an individual, R, makes an earth through his body, as shown in Fig. 6, he alters the distribution of potential between A and B and between B and C, and consequently the flow of electricity in each of the two devices, A B and B C. But in order that this person should receive a permanent shock his body must be traversed by a current, and this, to get to the other pole, must flow through A B, which is impossible.

In all the preceding remarks I have assumed that the resistance in the condenser circuit is zero, which is not the case, since the circuit comprises the earth. To make the device work properly it would, therefore, be as well to branch off partial inductances at intervals, especially if the circuit is very long and consists of unarmoured cables. We then obtain the arrangement shown in Fig. 7, whose resemblance to Prof. Silvanus Thompson's transatlantic telephonic device is worthy of notice. The point connected to earth in each choking coil is that which divides them into two parts inversely proportional to the capacities of the two cables. In the case of concentric cables, which is in practice one of the most important, the danger of contact is evidently localised upon the middle conductor, and it is sufficient in order to improve the conditions of safety to connect the outer conductor to earth through a suitable inductance (Fig 8).

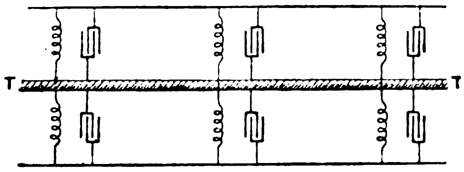

Fig. 7.

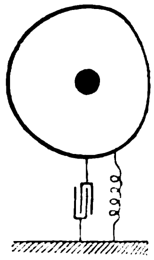

Fig. 8.

There is one point which I have up to now left unnoticed. I observed that the object of the addition of the inductance was not to modify the value of the difference of potential between each cable and earth, but to render this difference of potential unstable and reducible to a small figure the moment any body touched a conductor. But it is none the less true that the potential to which the body would be submitted, varying from 1,200 to 0, whilst that between A and B increased from 1,200 to 2,400, we have to do with the variable state. Hence we must take this fact into account. The steady state will be reached the sooner for the inductance the greater the resistance, whilst for the capacity it is the reverse. Hence there will no longer be at every instant exact compensation between the influences of the capacity and of the inductance, hence the human body concerned will be traversed by a current until the steady state is reached. But if we put things at their worst, that is to say, if we suppose contact to be made at the precise instant of maximum electromotive force, and if we neglect the inverse action of the inductance, we have the body subjected to the discharge of a capacity equal to that of the line charged to a potential equal to half the maximum potential difference. Is this discharge likely to be dangerous? On investigating what will happen, one is led to conclude that it will not be dangerous. In fact, accidents due to

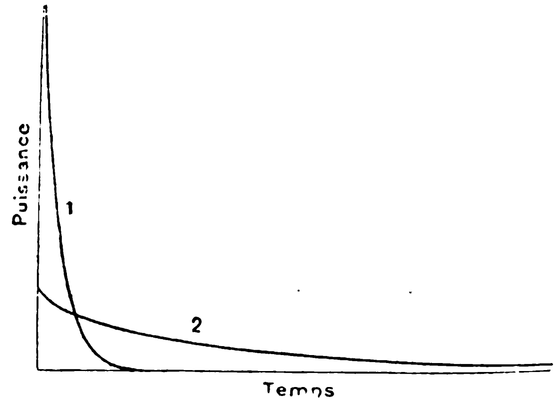

Fig. 9.

electricity are of two kinds—those due to shock and arising from the discharge of powerful condensers charged to static potentials, and those due to the passage through the body of permanent currents, causing death by the prolonged stoppage of the heart and lungs. It is evident, first of all, that we need not consider the latter case, since the variable period is only a very small fraction of a second. On the other hand, from the point of view of shock, one frequently receives, without inconvenience, the discharge of Leyden jars, having, it is true, very little capacity, but charged to a very high potential, and in which the energy, increasing as it does with the square of E ($\frac{1}{2} C E^2$), may be very considerable. Even assuming the quantity of energy in a network to be equal to that in a Leyden jar, the discharge of a Leyden jar is, from the point of view of shock, far more serious, since, owing to the higher pressure, the initial current, and especially the initial power, are much greater than in the case of the dis-

Digitized by Google

charge of a network. We may, indeed, represent the two discharges as in Fig. 9, where the curves 1 and 2 enclose equal areas. In other words, in the case of a Leyden jar the same quantity of energy traverses the body in an infinitely shorter time, and must therefore cause a much more violent shock. And since Leyden jar discharges do not result in grave consequences, we are led to the conclusion that *a fortiori* the discharge from a network will be harmless.

There can, therefore, be no doubt about the efficacy of this system and about the need of employing it. Moreover, when it is possible to combine it with one of the two methods previously discussed, that is, when it is possible to balance a capacity, made as small as possible by the methods I pointed out, by an inductance, we can obtain working resistances of the order of hundreds of thousands of ohms.

I cannot conclude without calling attention to a curious consequence arising out of the preceding considerations. Since, do what one will, the working insulation of an alternate-current system of distribution cannot reach even a few hundred thousand ohms, it is absolutely useless to sink large amounts of capital in obtaining an extraordinary insulation when the current is not on. All that need be required is that the ohmic insulation should be appreciably superior to the apparent insulation, so that one and even half megohm for each lead will be amply sufficient, provided we are sure of its maintaining that value. We may, therefore, enunciate this apparently paradoxical doctrine that, contrary to what has hitherto been thought, the insulation of high-pressure alternate-current distributing systems may be comparatively neglected, and that it would be much better to devote all our attention to the low-pressure continuous-current distributing networks, the deterioration of which by electrolysis can only be avoided by the use of very high insulation.

DISCUSSION.

R. ARNOUX: I should like to ask M. Claude what experiments he has carried out to corroborate his theories from the physiological point of view, which is the practically interesting one. I should also like to know if M. Claude has been able by his device to reduce the capacity current *sufficiently*, that is to say, to such a point that there would be no danger in any one touching a "live" network at any point. It is not necessary to reduce the current to zero, but to about 0·01 ampere. Above this amount one cannot get away from the circuit; below it one can. It is the current we have to limit, and not as is generally supposed the difference of potential. It is very difficult to even approximately adjust a capacity and a self-induction, and I should like to know how this is to be done in practice. Certainly nothing that may safeguard human life can be without interest to us, but I must confess that *experimental proof* seems to me in this case more than in any other to be absolutely necessary, if only to avoid the evil of over-confidence. With care the experiment could be carried out without danger. I am aware that my language is that of a practical man, but I think it is the language of prudence.

G. CLAUDE: I am in absolute agreement with M. Arnoux; I recognise the necessity of experimental corroboration. Since the danger to life depends on the current traversing the human body, it is at a maximum when the resistance is zero. Now take the case of an insulation of 2,000 ohms and a pressure of 2,400 volts, and suppose that by the addition of self-induction the resistance is brought up to 50,000 ohms. In the first case the body is traversed by 2,400/2000 = 1·2 ampere, in the second by 2,400/50,000 = 0·05 ampere, a harmless current on M. Arnoux's own showing. Even if experiment does not show that my device eliminates all danger, I should be inclined to apply it. Of two evils let us choose the least, and 50,000 ohms in series with the body would always be a safeguard worth having.

INSTITUTION OF ELECTRICAL ENGINEERS.*

MR. ALEXANDER SIEMENS' PRESIDENTIAL ADDRESS.

In taking this chair, and in thanking you sincerely for having elected me to be your President during this year, it is only natural that I should remind you of the fact that the late Sir Wm. Siemens was your first President. For this reason I may claim to be the first representative of the second generation of electrical engineers who have been called into separate existence by the founding of this Institution 22 years ago. During this period the Institution has grown from small beginnings to its present flourishing condition, thanks to the ability and energy of its founders and of my predecessors in this chair, who have spared neither time nor trouble to secure for electrical engineers the position to which the growing importance of the applications of electricity entitles them. In these endeavours they have been most ably assisted by the permanent staff of our Institution; but the greatest aid has been the benevolent friendship of the parent Institution and its officers. The permission to use this hall for their meetings started the Society of Telegraph Engineers with a standing in the engineering world that it would have cost years of work to achieve elsewhere; and the kindly counsel of the veteran Secretary of the Institution of Civil Engineers has often guided the Society in times of difficulty during the period of infancy, and we sincerely hope that he will long continue his useful work in this building.

* Delivered January 11, 1894.

The contrast which exists in the applications of electricity at the time of the founding of this Institution and at the present time has been so clearly and ably put forward by Mr. Preece in his address last year, that it would be wasting your time if I entered into any details to illustrate the progress. On the other hand, it may not be out of place to analyse the various factors which have influenced the development of our profession from the time at which telegraphy was the only important practical application of electricity until now, when it is called upon to supply energy for an immense variety of purposes. During the past 22 years our profession, and with it the Society of Telegraph Engineers, have changed their character, until these and the scope of their activities have become much more comprehensive, and much more intimately connected with the everyday life of the general public. With reference to this, telegraphy may be compared to the railways, as they both are for the indiscriminate use of the general public, and it is only an exception if a railway or a telegraph line is constructed for private purposes only. For working both these lines a special staff is required, and general rules for their use have to be adhered to by everybody; while in the modern applications of electricity the chief aim is to distribute the electrical energy so that each individual user can apply it in the manner and during the time that it best suits his convenience.

I need not recapitulate the reasons which for a long time made this distribution of electrical energy commercially impossible; but when these difficulties had been overcome, and the electrical engineers were ready to supply the public, it was found that, excepting the Corporation of the City of London, there existed no authority in the United Kingdom that could permit the laying of underground mains, and that a special Act of Parliament was requisite. To the unsophisticated mind this appeared to be extremely simple, as all that was needed was to extend the powers of the various authorities to whose care the laying of water and gas pipes and of telegraph lines was entrusted, so that they could deal in a similar manner with electricity mains. Some of the electric-light companies were of opinion, however, that the same object would be attained if they received powers from Parliament to make agreements with the local authorities, subject in every case to the approval of the Board of Trade, for establishing a system for distributing electrical energy in the various districts; and in pursuance of this policy several private Bills were filed for the session of 1882. The Government of the day did not consider it to be of public advantage that a limited number of electric-light companies should have such roving powers, but brought in a general Bill with the intention of facilitating and expediting the general application of electricity. With this object in view powers were to be given under the Bill to the Board of Trade to grant licences or provisional orders to electric-light companies. The licence to establish a system of electrical distribution in any district was to be granted to an electrical company who had succeeded in gaining the consent of the Local Authority; and its conditions were to be settled between the Local Authority and the Company, subject to some general provisions to be drawn up by the Board of Trade, and subject to the sanction of the Board of Trade. In districts where the Local Authority objected, the electric light company should, nevertheless, be able to establish itself by means of a Provisional Order of the Board of Trade; but to obtain this the company had to prove that the majority of the inhabitants of the district desired to have facilities for obtaining electrical energy. It will be observed that in this draft the license was intended to be the usual way of obtaining power to lay underground mains, and the formalities for settling it were extremely simple; the Provisional Order, on the other hand, was to be resorted to in exceptional cases as a means of overcoming the objection of Local Authorities. This is confirmed by the fact that in the draft the duration of the licence and of the Provisional Order were equal. These benevolent intentions were, however, thoroughly upset during the passage of the Bill through Parliament, and the Electric Lighting Act (1882), which was the outcome of the discussions before a select committee, has given rise to angry denunciations on account of the obstacles which, in the opinion of many, it was raising to an early introduction of lighting by electricity on a large scale.

Curiously enough nobody, during the passing of the Act or afterwards, seemed to care much about the fate of the licensing system, which was completely stripped of its importance, and alluded to by the learned counsel on both sides as suitable only for experimental purposes. Following up this train of ideas, the duration of a licence was curtailed to seven years. Had the intention of the Government, however, been carried out as at first designed, we should now enjoy in the United Kingdom the same facilities of establishing electric supply systems that have aided the development of the electrical industries so much in other countries, instead of being obliged to apply to Parliament in each separate instance at great trouble and expense.

Digitized by Google

Disregarding entirely this vital alteration of the Bill, another provision was seized upon to explain the failure of so many electric enterprises to which the aid of the public had been invited about that time ; you all know that this was the clause giving the local authority the right to buy out the electrical company after the lapse of 21 years, paying only the market value of the plant. This agitation was continued until, seven years later, the objectionable clause was modified, and in consequence of this alteration it was said that the confidence of the public in electrical enterprises had been restored. At the same time the system of granting powers by way of a licence was practically dropped altogether, and since then the Board of Trade has declared its intention not to grant provisional orders to electric light companies unless they have obtained the consent of the local authority, thereby abandoning entirely the original object of the provisional orders.

The ultimate result of all this legislation has, therefore, been to create a number of difficulties in the establishment of distributing systems in the United Kingdom ; in fact, the formalities of applying for a provisional order are very similar to those required for a private Bill, so that practically we are not in a very much better position than before the passing of the Electric Lighting Act (1882).

In order rightly to understand the influence which this legislation exercised on the development of the electrical industry, it is necessary to examine into the character and the number of the applications made to the Board of Trade under these Acts, and to trace how many of them have led to the establishment of distributing systems. Taking first the case of the electric light companies, or, as the Act calls them encouragingly, "the undertakers," we find that in 1883, 55 provisional orders were granted, all of which have been revoked; in 1884, 3 provisional orders and 1 licence were granted, all of which have been revoked ; in 1885, 1 licence was granted for the lighting of St. Austell, and this has been put into operation ; in 1886, 1 provisional order was granted to the Chelsea Electricity Supply Company: this also has been carried out; 4 licences granted during the two following years, 1887 and 1888, have since been revoked ; so that, up to the time of the passing of the amending Act (1888), 1 licence and 1 provisional order are the sole survivors. These facts clearly indicate that under the Electric Lighting Act (1882) the undertakers have not succeeded in their object to make electrical energy obtainable as a household commodity. It is, of course, quite another question whether there were not very strong causes of another kind which prevented the powers obtained under the Act from being exercised.

Since the Electric Lighting Act (1888) was passed, a new impetus was given to these enterprises, and, without examining the result of each year's applications separately, the grand total of the undertakers' efforts is that since 1882, 138 provisional orders have been applied for, and 15 licences ; of these, 81 provisional orders and 9 licences have been revoked, so that 57 provisional orders and 6 licences are still in force. To this number 2 provisional orders have to be added, which have been transferred from local authorities to undertakers. An electric supply has been established, or the work is actually taken in hand, in 54 cases, and about 53,000 H.P. will be available. On the other hand, of local authorities, a few had obtained powers under special Acts. The City of London, as mentioned above, had been able to make some experiments of street-lighting without any special permission ; but a number of them availed themselves of the opportunity given by the Electric Lighting Acts, and obtained 121 provisional orders and 6 licences up to the end of 1892. Of this number, 8 provisional orders and 4 licences have been revoked, or merged in provisional orders, so that 113 provisional orders and 2 licences granted to local authorities are still in force ; but two of the provisional orders have been transferred to undertakers, as mentioned above. Under these powers 51 electrical systems of distribution, with 35,000 H.P., have been established, or are in course of construction, while in almost all the other instances the intention soon to carry out the work is apparent. With your permission, a table, giving the details of all these applications and of their fate, will be added to the Address, if you consider it worthy to be printed in the transactions of our Institution.

From the figures which I have given, it is, however, plainly apparent that the local authorities will very shortly have a good many more stations at work than the electric lighting companies ; and, in my opinion, this is as it should be. The financial success which has invariably attended the municipal electric enterprises has relieved the rates at the expense of the wealthier classes in a perfectly legitimate manner ; and the more electricity becomes one of the common necessaries of life, the better it is that its supply should be in the hands of the community, and not in those of monopolists.

A strange fact in connection with this subject is that the great majority of the local authorities should have waited until the passing of the Electric Lighting Act (1888) before applying for powers to supply electricity, for it must not be forgotten that their position was in no way affected by the alteration of the Electric Lighting Act (1882). The explanation must perhaps be looked for in the exaggerated expectations that were raised by the statements of company promoters in the year 1882, when the most reckless assertions were made as to the results to be obtained by establishing electric systems of distribution. The natural consequence was that the inquiries set on foot by various local authorities in no way confirmed the sanguine estimates that had been dangled before the public to obtain its support ; and the total failure of the electric light companies to carry out a single one of the orders and licences obtained by them in the years 1883 and 1884, made the local authorities hesitate before they embarked the ratepayers' money in such precarious undertakings. Fortunately for the progress of our industry, there were some Corporations who could be convinced by the result of their inquiries that the use of electric light would be very advantageous for a variety of purposes, and that the knowledge and ability of the electrical engineers had progressed sufficiently to make a profitable distribution of electricity from a generating centre possible. We have seen that their example has been largely followed, and there is every prospect of a continuous and ever-increasing development of this branch of electrical engineering.

To be sure, in foreign countries, especially in the United States, the use of electricity is much more common than here ; but this is the natural outcome of the greater facilities for establishing centres of supply under the laws of the various countries, where the local authorities in the majority of cases have the power to make agreements with electrical companies for supplying the district with electrical energy for various purposes. Another important factor in retarding the spread of the applications of electricity in this country is the otherwise very laudable desire of the electrical engineers to show in every new undertaking a distinct advance on its predecessors. In this way the details of constructions are undergoing a constant change—in strong contrast to the United States, where the leading manufacturers have their standard sizes of plant and accessories ; these are manufactured wholesale by specially designed machinery, and can, therefore, be supplied much more cheaply than apparatus specially constructed for each case. At the same time the whole transaction is greatly simplified by the absence of long negotiations about the construction of the apparatus, the town which is to be lighted simply specifying how many glow lights and arc lights are to be supplied. This system of working has certainly been instrumental in accelerating the introduction of electricity for a variety of uses throughout the States ; but it can hardly be pretended that such a cast-iron application of the same apparatus under a variety of circumstances can lead to the most economic results, nor has it been possible to keep up the quality of the work to the English standard. Those of you who have visited the World's Fair at Chicago last year, and have examined a little into the details of workmanship and design, will doubtless agree that Sir Richard Webster was fully justified, in his address to the Society of Arts, in contrasting the American and the English exhibits in this respect, very much in favour of the latter.

However much other causes may have contributed to delay the development of electrical engineering, it is clear that the principal one must be looked for in the exaggerated expectations that were raised, either by ignorance or by design, when the general public first seriously thought of regarding electricity as a commodity for everyday use. At that time the promoters of electric companies preached to the public that electricity was in its infancy, that the laws of this new science were totally unknown, and that wonders could be confidently expected from it. There was a short time of excitement to the public and of profit to the promoters ; then the confidence of the public in electricity was almost destroyed, and could only be regained by years of patient work. That the electrical industry was not altogether killed by all these adverse factors is undoubtedly due to the firm scientific basis on which it rests, and to the advantages which the applications of electricity possess as compared with other means for accomplishing the same ends.

In a discourse before the Royal Institution I had an opportunity of reminding the audience that during the last 60 years the most eminent scientific men have studied the phenomena produced by electricity, and that, in consequence, the laws which govern electric currents were perfectly well known when the supply of electricity on a large scale became commercially possible. Since that time the study of electrical phenomena has been carried on with even greater zeal than before, and electrical engineering is now in no danger of lagging behind for want of theories, but is largely aided in its progress by the painstaking investigations carried on in many laboratories, both in England and abroad. While electrical engineering is thus closely allied to physical science, it has quite as intimate a relation to mechanical engineering ; in fact, its real progress dates from the time when the close connection of electrical and mechanical engineering was thoroughly recognised ; and since then these two branches of engineering have reacted on one another to their mutual advantage.

The contrast between present practice and that of the pioneers of our profession is at once recognised in reading the first papers

Digitized by Google

and reports on dynamo-electric machines, where particular stress is laid on the small size and on the low weight of a dynamo to produce a given result; but the necessity of having the moving parts durable, and of not always working the machine up to its maximum power, was completely ignored in the desire to produce a large effect with the minimum expenditure of materials. A glance at a modern dynamo, especially when it is built on the same lines as a machine of 20 years ago, will at once reveal the progress of mechanical design that has taken place in the interval. The circumstance that at first only weak currents of electricity were utilised for practical purposes, and that during this period the electrical appliances were constructed like scientific instruments, had undoubtedly brought about this neglect of mechanical considerations, and a healthy re-action could only take place after the mechanical engineer had taken the management of the applications of electrical energy from the hands of the instrument makers. On the other hand, the requirements for driving dynamos to the best possible advantage have served as no mean incentive for mechanical engineers to introduce a number of important improvements into the design of steam engines; in fact, the class of high-speed economical engines may be said to have been called into existence by them, and this has led to the use of direct-driven dynamos, in which this country undoubtedly has taken the lead.

In another direction the governing of the speed of the steam engines has been vastly improved, although at first the mechanical engineers regarded the complaints of the electrical engineers simply as an excuse to shift the blame for the bad performance of their dynamos on to the steam engine. They very soon learned, however, the importance of running at an unvarying speed, and the result is that even comparatively cheap steam engines can be obtained nowadays that govern infinitely better than a high-class engine of 20 years ago. Originally the steam dynamos were designed for use on board ship, where economy of space is of importance, and great credit is due to the Admiralty for introducing very early a system of testing, which has been no small incentive to all concerned to improve the dynamos as well as the steam engines. In these tests the dynamo is run for a number of hours at its maximum output, and no part of it must get hotter than the surrounding air by more than a prescribed number of degrees of heat. Nothing could be simpler than this test, and at the same time it is the most reliable way of finding out whether a dynamo has been constructed suitably for its work. During the same run the water is measured which, in the form of steam, is supplied to the engine, and the relation between the water consumed and the electrical energy supplied to the electrical circuit determines the merit of the steam dynamo tested.

(To be concluded.)

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

C. B. Harness, Managing Director of the Medical Battery Company, J.M. M'Cully, and C.B. Hollier, surrendered to their bail on Wednesday last, before Mr. Hannay, at Marlborough-street, to answer the charge of having conspired together to obtain money by false pretences from divers persons.

The Rev. HENRY MONTAGUE VILLIERS, Vicar of St. Paul's, Knightsbridge, said that in September, 1893, he was suffering from an attack of neuritis in the right arm, and went to the Medical Battery Company. His medical man advised him to use electricity. At Oxford-street he saw Mr. Harness, who arranged that he was to pay three guineas for six applications of electricity. He was not examined by a doctor there. He was treated at the establishment with great benefit.

Cross-examined by Mr. TERRELL: He did not get an introduction when he went to Oxford-street, nor did he go there owing to advertisements he had seen. He went because he heard he could get good electrical appliances. Mr Harness was the first person he saw; he was taken direct to his room. Not a single word was said to him about buying a belt. He did not know that the treatment he received was called electrical massage. A current of electricity was applied to one of his nerves. When the sum of 24 guineas was mentioned he indicated that it was more than he was prepared to pay.

Re-examined by Mr. AVORY: He believed that it was Dr. Laird who treated him at Oxford-street.

CECIL D. GREENWOOD, M.R.C.S., L.R.C.P., said that in 1889 he was not in good health, and was suffering from a sluggish liver, indigestion, and insomnia, owing to overwork. He tried the experiment of using a Harness electropathic belt, which he obtained at the premises at Oxford-street, where he called from curiosity. He saw Mr. Harness there, and told him that he was a medical man. Mr. Harness gave him a belt to experiment with. He wore it, with the result that in a fortnight he was practically well. At intervals he had worn a belt ever since. When the first belt was worn out he got another. On August 23, 1889, he sent a testimonial to the Company, speaking highly of the beneficial results which he had experienced from using the belt. He had recommended about 12 of his patients to use the belts, with, in most instances, good results.

Cross-examined by Mr. TERRELL: The old belt that he had discarded he had broken up to make therapeutic experiments with. At the present moment he was wearing one of the belts. It was a connected belt. In the first belt there was no connection between the discs, and nothing was said to him about connecting them. He had nearly always worn the belt next his bare skin. The reason why he had not always worn the belt next his skin was, that it produced sores at first. That was at the time when it was unconnected. He had not made experiments to test its electrical properties. His experiments were limited to finding whether it would cure or not. Successful results had followed the wearing of an ordinary warm belt. He had seen Mr. Harness altogether about a dozen times. He had never reported to Mr. Harness the experiments he made with the belt. They led him to a result which was not consistent with the wearing of an ordinary belt. Before he wore a Harness belt he wore an ordinary flannel belt, which did not produce the same result as the Harness belt. The difference between the Harness belt and an ordinary flannel belt was that one produced electricity and the other did not. He only knew that from what he had been told. He had no special knowledge of electricity, other than that which any medical man had. He could not say whether unconnected zinc and copper plates would produce electricity when placed on the body.

Re-examined: A great deal of his knowledge of medicine was from his reading, combined with his practice. He was quite certain that it was an unconnected belt that cured him. He never received any fee from the Medical Battery Company, and got nothing for writing the testimonial, which was quite spontaneous. He looked upon sores caused by wearing the belts as a proof that electricity was generated.

Mrs. SOPHIA MIDDLETON stated that four years ago she was suffering from neuralgia, and went to four medical men who did her no good. She then went to 52, Oxford-street, and purchased a belt and spine-band, paying five guineas. She wore the belt for about a month, and the spine-band for several months, with the result that she was cured. About two years ago the neuralgia returned, and she went again to Oxford-street to have a course of electrical treatment. She was under treatment by statical electricity for about six weeks, going there nearly every other day. She paid 50 guineas, and gradually got much better.

The Rev. EDWARD FRANCIS SHAW deposed that five years ago he purchased a battery and belt at 52, Oxford-street. He paid six guineas for the battery and three guineas for the belt. He got the belt on the understanding that it only generated a slight quantity of electricity. He wore the belt for nearly four years. He applied the battery to the belt. Sometimes he wore the belt without applying the battery to it. He had a tender throat from overwork, and that induced him to try the treatment, which did him very much good. He had tried other remedies with no avail. He was satisfied that the appliances he got at Oxford-street had cured him entirely. He had studied science and had lectured upon astronomy. He did not believe in imagination, which was the author of all error. He believed he was cured by electricity.

Cross-examined by Mr. TERRELL: He was a strong believer in the efficacy of electricity. He had not studied electricity.

In re-examination the WITNESS said that he had a slight knowledge of electricity. From his knowledge he felt convinced that the belts were electrical.

Mr. HANNAY at this point adjoined the further hearing of the case till next Monday afternoon.

Re the Printing and Telegraph Company of the Agence Havas —ex parte Cammell.

In the Chancery Divison, before Mr. Justice Stirling, this week an action was brought which raised a question of some importance in company law relating to the liability of directors in respect of their qualification shares, and also gave the public an insight into the manner in which public company issues "go to allotment." It was a motion by Mr. Charles Cammell, of Marshfield, Chippenham, asking that the register of members of the above-named Company might be rectified by removing his name therefrom as holder of forty shares, on the ground that he never applied for or agreed to take or accepted the allotment to him of the said shares, and that such allotment, if made, was improper and invalid. The Company was formed in March last, and Article 62 of the Articles of Association provided that the first Directors should be appointed by a majority of subscribers to the Memorandum of Association. Article 64 provided that the qualification of a director should be the holding of £200 of share capital, in respect of which all calls for the time being due should have been paid; and this qualification was to apply as well to the first directors as to all future directors, but such first Directors should be allowed one month from the first general allotment of shares of the Company in which to acquire their qualification. By Article 70 the office of Director was to be vacated (*c*) if he ceased to hold the requisite number of shares, or in the case of a first Director, if he failed to get them within the prescribed time; (*d*) if he should send in a written resignation to the Board, and the same should not be withdrawn for seven days, or be previously accepted. The applicant signed the Memorandum of Association for one share, and was appointed a Director. On March 19th the first Board meeting was held, which the applicant attended. On March 29th the second Board meeting took place, but the applicant was not present. At this meeting resolutions were passed for the allotment of shares in accordance with certain allotment sheets, which included the name of the applicant in respect of forty shares, for which, however, he had made no application, and he was put on the register of shareholders. On May 7th the plaintiff wrote formally resigning his position as Director. In July the plaintiff first heard that his name had been put on the register, and wrote to the secretary asking that it should be removed. To this the secretary answered that the applicant's letter should be placed before the Board. In September the applicant received notice calling on him to pay £85 in respect of the shares. On November 1st the notice of motion was given by which the applicant sought to have his name removed from the register of shareholders in respect of all the shares in his name, except the one for which he signed the Memorandum of Association.

Digitized by Google

Mr. Justice STIRLING, in giving judgment, said: I think that upon the evidence it must be taken that until May 15th the applicant was unaware that any shares had been allotted to him. The first question to be considered is whether the applicant has agreed with the Company to take the 39 shares in question from it. Express agreement there is none. Can any be implied? The applicant no doubt acted as director, but this was not sufficient. The applicant had bound himself to conform to the regulations contained in the articles, including, of course, those as to the qualification of directors. There is no provision in the articles that the directors shall take the shares required for qualification or be liable as if they had taken them. There is only a provision that if a director does not acquire the requisite number of shares within a limited time he shall cease to be a director. That regulation makes it his duty not to act after the prescribed time, but that is quite different from a regulation that if he continues to act he shall be deemed to have contracted to take them. In this case the name of the applicant had been entered on the register as the holder of the shares allotted to him on March 29. If the applicant had been aware of this, I should readily infer an assent on his part to take the shares; but I think he did not actually know it until the middle of May, and I also think that he cannot be fixed with constructive notice of the fact. But although the applicant may not actually have agreed to take the shares, either express or by implication, he may have so acted as to preclude himself from denying that he has entered into such an agreement, and the main contention on the part of the company has been that he did in fact so act. I think he cannot be taken to have acted in respect of a qualification, or be held to have estopped himself from denying that he agreed to take the shares in question. In my opinion, therefore, the name of the applicant was entered on the register without sufficient cause, and he does not appear to be precluded by anything which has happened from having his name removed. There must, therefore, be an order in accordance with the notice of motion.

Judgment for the applicant accordingly.

Royce and Co. v. Cuthbert.

At the Hull County Court an action was brought by Messrs. Royce and Co. to recover £38. 10s. 6d. from the defendant, Mr. Alfred Cuthbert, lessee of the Theatre Royal, Hull. Messrs. Royce and Co., in December, 1892, installed the electric light in the theatre, which was sufficiently completed for use on the Boxing Day of that year, and it was so used. In March last the first instalment of £100 was paid, and a further sum of £50 in August following. The balance was due in October, and this action was brought to recover this balance, with some extras.

For the defence it was stated that the terms of the contract had not been carried out.

Judgment was deferred.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 6, 1894.

The General Electric Company.—The General Electric Company has at last "taken the bull by the horns," and instead of continuing to maintain an attitude of defiance toward its critics and denying all reports reflecting upon its affairs, has finally come down to a basis more in accordance with its changed condition. The great works at Lynn are to be almost entirely abandoned, and the expensive and multitudinous offices in New York and Boston abolished. All manufacturing and business interests will be concentrated at the Schenectady works. The lamp works will remain at Harrison, N.J. This move implies that the New York or Edison interests in the Company have got the upper hand, and the next thing to expect is a rival New England organisation composed of the former Thomson-Houston interest.

The Telephone Situation.—The expiration of the Bell diaphragm receiver telephone patent on January 30th will direct strong attention toward the Government-Berliner suit, which may develop into a scandal of no mean proportions. It will be remembered that the Berliner patent on variable resistance contact was kept in the Patent Office for 14 years by means of interferences, all said to have been collusive, thus extending the monopoly to that extent, and presenting the anomaly of a main patent being issued after a number of its subsidiary patents had expired.

New Electrical Manufacturing Enterprises.—Two large Western manufacturing companies have commenced to extend their activity to the electrical field; one of them, the Walker Company, of Cleveland, O., to manufacturing electric street railway apparatus. As both are conservative firms, and there is no suspicion of stock-jobbing or dependence on patents, the new departure is significant, and an indication that in a few years the electrical industry will have settled down to the same basis as any other business.

CORRESPONDENCE.

INSULATION RESISTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

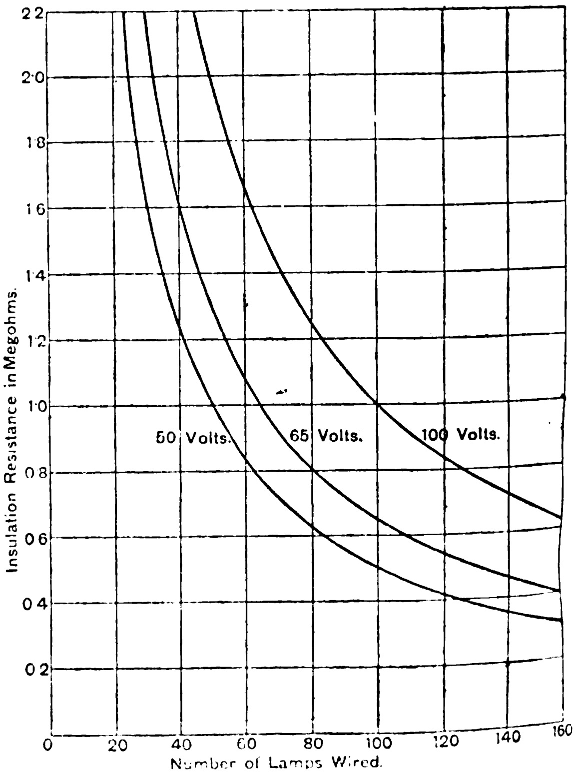
SIR: The article in your columns of last week on the rules in vogue dealing with the insulation resistance in house wiring is highly interesting and instructive, the diagram making painfully apparent the extraordinary differences in the numerous rules on this important subject.

It certainly is desirable that some change in the direction, if possible, of a standard formula should be adopted, applicable to the various conditions of supply.

There are, first, the two and three-wire systems of our public companies, and next, the private installations of a low voltage, to be considered. It will be noticed that of the numerous rules you quote, not one takes into consideration the E.M.F., and yet surely, when dealing with insulation, the voltage is an important factor.

Next, we have to consider the number of lamps (irrespective of their candle-power), as they practically govern the surface leakage due to switches and cut-outs. Hence the Bradford rule (10 megohms ÷ amperes) is scarcely satisfactory, and an arbitrary insulation per lamp is not sufficiently flexible to meet the varied conditions of supply.

If, however, we take the volts as our constant, and divide them by the number of lamps, and let the product represent the resistance in *megohms*, we have the simple formula $\frac{\text{E.M.F.}}{\text{lamps}}$ = megohms, and one that squares very fairly with modern practice.



Taking the range of lamps, as per your diagram, and the voltages mostly in vogue, we obtain the following results:—

Lamps.	I. 50 volts.	II. 65 volts.	III. 100 volts.
20	2·5	3·25	5·0
40	1·25	1·62	2·5
60	0·833	1·08	1·66
80	0·625	0·81	1·25
100	0·5	0·65	1·0
120	0·416	0·54	0·833
140	0·357	0·46	0·714
160	0·312	0·40	0·624

Columns I. and II. would mostly apply to private installations, and Column III. to the majority of our public supplies. All that is now needed is to fix a maximum and minimum to meet the extreme ranges—say, 5·0 Ω and 0·1 Ω respectively. Upon plotting the above it will be found that columns I. and II. give curves closely corresponding with T on your diagram, while column III. is above that of A, but exacts nothing beyond what is attainable with good work.—Yours, &c.,

11, Lombard-street, January 16, 1894. H. HUMAN.

ELECTRIC TRACTION IN LIÉGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Page 262 of your valuable paper (issue of the 12th inst.), you refer to "Electric Traction in Liége," and describing briefly the plant, you say that much of the experience of American engineers has been disregarded in the construction of the line. As I have been connected as consulting engineer with the Company who has built the line, I hope you will allow me to reply to your information by the following statements:—

(*a*) The overhead construction has been made according to American experience; insulating materials are of American patterns.

(*b*) The motors, controllers, trucks and cars have been designed in Belgium, according to American engineers' experience, and they might be compared favourably with any American made at the time the line was started.

(*c*) The power station is not furnished with high-speed American steam engines, and the reason is that the contractors purchased in Belgium moderate-speed engines (150 revolutions per minute), which run the plant economically, the amount of coal burned in the boilers being only three pounds per car kilometre.

I am myself sincerely convinced that the American engineers have had the largest experience in electric traction, and I have tried to carry out their ideas in Belgian practice. The Compagnie Internationale d'Electricité, from Liége, who were the contractors for the plant, are now associated with the Thomson-Houston Company in Belgium, and that fact leads me to think that I have succeeded in convincing the Belgian engineers of the value of American practice in electric traction.—Yours, &c.

27, Rue de la Sablonnière, Bruxelles, W. DIERMAN.
January 13, 1894.

THE ELECTRICIAN AND THE BRIGHTON COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Brevity is undoubtedly the very soul of wit, but at the same time the wit is liable to lose a great portion of its charm when it displays a palpable lack of verisimilitude. I do not think I am wrong in adding that this is one of the accepted canons of journalism, and I am therefore extremely surprised to find in the last issue of *The Electrician* a statement which shows a very reckless disregard to this rule.

In your article upon the Newport tenders you comment upon the Brighton and Hove Electric Light Company's business and in a statement, as conspicuous for its illogical reasoning as for its brevity, you declare its value should be marked "Goodwill, £5,000; plant, *nil*."

Now, I have no concern whatever in regard to your title to call into question the procedure on the Newport tenders, but when you declare that our plant is valueless I claim the right to refute such an absurd and libellous statement, and I protest against your attempt to depreciate the asset which is in our possession.

Will the Electric Construction Company feel grateful for your declaration that four of their 70-unit alternators are worth nothing? Are you paying a compliment to the Westinghouse Company by naïvely telling them that the value of some hundreds of their Shallenberger meters is *nil*? Do you think the Brush Company will thank *The Electrician* for the information that Mr. Mordey's famous alternator and converters besides three of their 40-light machines are not worth anything? And the Cardew voltmeters, the Sir William Thomson ampere balances, Fowler's engines, the Electric Construction and the Leeds and London transformers; is it, after all, your opinion that the value of these can be marked up *nil*?

We are convinced that all the machines and instruments mentioned above, which are in our possession, are of first-class value, and your unwonted statement that our plant is *valueless* is as unfair to us as it is injurious to the reputation of the manufacturers. Moreover, it can only be very prejudicial to our interests in the realisation of the concern, and I have to ask you to retract your statement no less prominently than you gave it publicity.—Yours, &c.,

G. W. SPENCER HAWES, Secretary.

THE NEWPORT TENDERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is, of course, quite excusable for the editor of a technical journal to be unaware of business methods, but when he presumes upon his ignorance to the extent of ridiculing a business document as some class of "interesting game" he lays himself open to a charge of unfairness. My remarks, of course, have special reference to the manner in which you dealt in your last issue with my report on the tenders for electric lighting plant submitted to the Newport Corporation. Treating the document, as you do, as a huge joke from beginning to end, your readers may be glad to hear my view of the matter.

Some 60 tenders were referred to me for examination and report, and I coped with the task in a document, eventually ordered to be printed, of 50 pages. It would involve too great a claim upon your space to explain the report in detail, but in order to show the principle underlying the method which you hold up to ridicule I will confine my remarks to three 150-I.H.P. engines, for which 19 tenders were submitted. I give sample details of some of them:—

Three Engines, each to give off 150 I.H.P.

	Size of Cylinders.		Stroke.	Speed.	Bearing surface (per main bearing).	Steam consumption in lbs.	Efficiency.	Price.
	High Pressure.	Low Pressure.						
	in.	in.	in.		sq. in.		%	£
A.	11	20	30	110	72	16	93	2,520
B.	14·5	24	24	110	80	16 to 17	85	2,450
C.	13	24	24	110	112	18 to 20	86	2,337
D.	14	23	32	85	84	18	90	2,190
E.	12	18	33	100	77	18	80	2,139
F.	11	21·5	30	100	49·5	18 to 20	80	1,950
G.	12	20	24	110	55	19	91	2,262
H.	11	20	30	100	60	14 to 15	85 to 90	2,685

It will be noticed that though all the engines are guaranteed to do the work required of them they differ considerably in price. The offers are all from first-class makers, and I am puzzled to gather from your remarks how you would deal with the task of selection. Your reproach is that I did not "simply recommend one tender in each class with or without reasons." I preferred to clearly show my principals the nature of the choice that lay before them.

To have simply recommended the tender which named the lowest price would have been unfair to the other tenderers, who were prepared to offer engines of a better class. To bring all the *pros* and *cons* to a level I chose a standard, and in order not to make an invidious choice I selected the standard arbitrarily. I then proceeded, simply for the purpose of comparison, to appraise in each case of variation from the standard the approximate money value of that variation. I fully explained the method by which I arrived at these approximate values, which, applied to all the engines alike, were fair to all. To make the method clear I may state that, in the case of the engine I took as a standard:—

Size of cylinders { High pressure.............. 14in. diameter.
Size of cylinders { Low pressure .... 23in. „
Stroke.. 32in. „
Speed 85
Volume swept by the pistons per minute = 3,060,000 cubic inches.
Bearing surface (per main bearing) 84 square inches.
Steam consumption, 18lb.
Mechanical efficiency, 90 per cent.

Digitized by Google

with the result that the engine "A" had to be penalised as follows:—

Bearing surface (assuming that the other parts of the engines bear a like proportion), standard 84 sq. in. for 85 revolutions, for 110 revolutions, should be 108 sq. in. Deficiency, 36 sq. in., at £1 per square inch per engine		£108
Volume swept by the pistons per minute standard = 3,060,000		
Against	2,640,000	
Deficiency	420,000	
At 5s. per 1,000 cubic in.		105

and credited with:—

Mechanical efficiency	93	
Standard	90	
Allowance	3	
At £30		90
Steam consumption (*i.e.*, 2lb. × £163, basis of consumption being 18lb.)		326

Dealing with each engine in this way I was able to arrive at a fair comparison, by which it appeared that engine D gave the best value for money. If any one of your readers can suggest a sounder method of dealing with such tenders I shall be glad to know of it through your columns.

With regard to the remainder of your article, I cannot conceive why you should do such an injustice to the "pioneer" Brighton Station as to characterise its plant as *nil*. It is, I think, generally regretted in the electrical profession that the Brighton Corporation did not see fit, when they embarked in electricity supply, to take over the "pioneer" station then supplying Brighton, and personally I regret, to the tune of a good many thousands, that I did not then succumb to the inevitable, and recommend the abandonment of the enterprise instead of extending the works; but it is hardly generous on your part, at a time when negotiations are pending for the sale of the plant, to write down its value as *nil*, especially when the plant is about the counterpart to that which is working so satisfactorily in Dublin, Leeds, Eastbourne, Blackpool, West Brompton, and Madrid.

I pass over your innuendos to the effect that, as a consulting engineer, I find it is impossible to act independently when the tenders of Messrs. Fowlers are under consideration. Strange as it may seem to your leader writer, I feel quite able to exercise a perfectly impartial and fearless judgment when the interests of the Newport Corporation or any of my other principals are at stake.—Yours, &c.,

ROBERT HAMMOND.

117, Bishopsgate, London, E.C., January 15, 1894.

[As the report on the tenders is public property, we give the names of the engine makers referred to in this letter:—

A.—Yates & Thom.	E.—Brush Company.
B.—Jas. Watt & Co.	F.—Copeland.
C.—John Fowler & Co.	G.—Cole, Marchent & Morley.
D.—Davey Paxman.	H.—Hick, Hargreaves.

—ED. *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES' DIRECTORY AND HANDBOOK" is in preparation, and will shortly be published. *New names, alterations of addresses, &c., should be sent in at once.* Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

TENDERS INVITED.—The Mayor of the Commune de Jassy, Roumania, invites tenders for contracting for the erection of the Théatre National. Amongst the contracts are included ironwork and skilled smiths' work, ironmongery, telegraphs and lightning conductors, waterpipes, creosoting, engineering work, an electrical installation, heating and ventilating appliances, appliances and fittings for lighting, &c. Either the whole or a portion of the work can be tendered for, and offers must be sent in to the Hall of the Mairie, by Thursday, the 3rd/15th February next, between 2 and 4 p.m., in writing. Particulars of the plans, &c., can be inspected at the Office of Works of the Commune, or on application to the architects, Messrs. Fellner et Helmver, Ix. Bez, Servitengasse 7, Vienna.

——— The Electric Lighting Committee of the Borough of Halifax invite tenders for the supply of an overhead travelling crane. Tenders must be sent in to Mr. Keighley Walton, Town Clerk, by 10 a m. on the 25th inst. Further particulars are given in our advertisement columns, and all information can be obtained of Mr. T. P. Wilmshurst, electrical engineer, Cripplegate, Halifax.

——— The Corporation of the borough of Great Yarmouth invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough, in accordance with the specification, plans, &c., which can be obtained of Mr. J. W. Cockrill, A.R.I.B.A., borough surveyor, Municipal Buildings, Great Yarmouth, after Tuesday next. Tenders, which may be for the whole or any part of the plant, &c., must be sent in to Mr. T. M. Baker, town clerk, not later than noon of Monday, February 19th. Further information concerning the specifications, &c., may be obtained from Mr. A. H. Preece, 39, Victoria-street, London, S.W.

——— Readers are reminded that the tenders for electric lighting plant required by the Edinburgh Corporation have to be sent in not later than the 30th inst. All information regarding these tenders can be obtained of Prof. A. B. W. Kennedy, 14, Old Queen-street, Westminster, S.W.

TENDERS ACCEPTED.—The offer of Mr. J. F. W. Bray has been accepted by the Corporation of Great Yarmouth for the erection of their electric lighting station for the sum of £2,626.

——— The tender of Messrs. Spagnoletti and Crookes has been accepted by the Baths, Cemetery, and Recreation Grounds Committee, of Burnley, for providing and fixing electrical fittings at the plunge baths for the sum of £50.

REMOVAL NOTICE.—Mr. Arthur H. Vesey, A.M.I.C.E., has removed his offices from the central station of the Chelsea Electricity Supply Company to Bradon House, George-street, Croydon.

LIQUIDATION.—A petition has been presented by Mr. James Stevens, of Rosherville, for the winding up of Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited), and is down for hearing at the Royal Courts of Justice on the 24th inst.

RE J. AND W. WEEMS.—The trustee in the sequestration of this estate calls a general meeting of creditors at the offices of Messrs. Thomson, Jackson, Gourlay and Taylor, 24, George-square, Glasgow, on Wednesday next, at eleven o'clock, for the purpose of electing a Commissioner in place of one resigning.

MESSRS. E. P. ALLAM AND CO.—This firm have just completed the electric lighting of the extensive range of offices and sample rooms of the Mazawattee Tea Company, Eastcheap, E.C. The firm have also several other lighting contracts in hand, or nearing completion.

BERLINER TELEPHONES.—Messrs. O. Berend and Co. have just issued list "T," which members of the trade can obtain on application. The list deals with the Berliner carbon pencil sets, Blake transmitter combinations, the "Universal" transmitter sets, battery sets, magneto generators, and, in addition, complete telephone exchange outfits. Telephone accessories are fully illustrated, and prices accompany the descriptions in each case.

THE "HARD" INCANDESCENT LAMP.—Messrs. Wilhelm and Co., of the Wool Exchange, E.C., inform us that they have already received orders for large quantities of the "Hard" incandescent lamp, for which they are the agents.

BROCKIE-PELL ARC LAMP.—In reference to our Trade Note last week that, amongst the contracts carried out by the Brush Company, was the supply of the whole of the electrical plant at Earl's Court Exhibition of 1893, we are asked to state that the arc lamps used were the standard Brockie-Pell throughout.

MANCHESTER EDISON-SWAN COMPANY.—This Company have recently built and opened extensive new show rooms at the Exchange Station approach, Victoria-street, Manchester, where stocks of the Company's specialties are also kept. Besides the ordinary show rooms, the Company have fitted up a complete suite of model rooms, furnished and arranged with a variety of electric light fittings to enable intending users to gather the general effect to be obtained from the various styles and designs. Amongst the fittings for which these model rooms are especially notable, are crystal

Digitized by Google

glass and gilt metal-work, an attractive design for a large electrolier being particularly noteworthy, the crystal lending itself very readily to artistic effect. A billiard room is included in the suite. Both gas and steam power is employed in generating the large amount of current necessary to keep the show rooms fully lighted, and this is an additional inducement to those contemplating putting in the light, as they are shown both steam and gas at work, and can judge for themselves which would be more suitable where isolated installations are under consideration. Visitors to Manchester should not miss the opportunity of inspecting the show rooms.

South Wales Institute of Engineers.—The new and handsome block of buildings in Park-place, Cardiff, the head-quarters of the South Wales Institute of Engineers, and of the Monmouthshire and South Wales Coalowners' Association, were opened this week. The building was commenced in July, 1891, and was completed this month, a long stoppage having occurred owing to the strike in the building trade. The block of buildings is partly lit by gas, but a complete electric light installation has been provided by Messrs. B. Verity and Son, of London and Birmingham. The electric light fittings are very tasteful, and everything is in readiness to connect the building on to the Cardiff Corporation's system when this is complete. At present the electric light supply is obtained from Cardiff Castle, by permission of the Marquis of Bute.

Messrs. C. A. Parsons and Co.—Included in a large number of contracts completed by this firm during the past year is the supply of turbine engines to the Newcastle and District Electric Lighting Company, the Cambridge Electric Supply Company, and the Scarborough Electric Supply Company, showing an aggregate of 1,400 H.P. A number of smaller plants of the steam turbine class and ordinary lighting plants for ship, mill, and private house lighting have been completed, giving a total of nearly 2,000 H.P. Orders for steam turbine motors of an aggregate of more than 3,000 H.P. are now under construction, including a 250-H.P. steam turbine alternator for the Portsmouth Corporation. Other contracts in hand include transformers for the Halifax Corporation and for the three electric supply companies mentioned above, as well as a number of search-light reflectors and other electrical specialities for the manufacture of which the firm are well known.

Electric Pianofortes.—Messrs. Grob and Co. notify that they have arranged with the Sherborne Electric Installation Company to exhibit their new type of pianos played by electricity. Instruments can be seen at the Sherborne Electric Installation, and inspection is invited.

Messrs. Faraday and Son.—In order to meet the growing demand for their No. 21 standard, with tilting silk shade, this firm have recently made reductions in price. The tilting shade, which is protected under Register No. 134,442, retains its position wherever placed.

Diaries for 1894.—The Eastern Telegraph Company present to their customers a very handy diary and pocket calendar for 1894, which, in addition to a list of chronological events of special interest to telegraph men, contains several useful tables, a neatly-ruled diary, and a set of admirable maps (of course, on a small scale), showing in red the cable systems of the world. The Company also issue a neat pocket memorandum book, in leather case, with medallion data and pencil. For the fourth year in succession the Company present a *papier-maché* paper-knife and calendar, with a neat map of the Eastern and Eastern Extension Companies' cable system printed thereon.

Calendars.—We have received from Messrs. Causton and Sons, of Eastcheap, E.C., a parcel of calendars in various forms, which will be found very useful for office and domestic use.

Aberdare.—The Local Board has recently held a special meeting to consider the application of Messrs. J. C. Howell and Co., for the Board's consent to a Provisional Order for the lighting of a portion of the town by electricity. Subsequently a vote was taken, and the Board's consent to the application was finally approved.

Bradford.—Following the example set by many of the local authorities throughout the country, the Town Council are collecting information in connection with the introduction of a refuse utiliser in conjunction with their electric lighting works. It is probable that a sub-committee will be appointed to present a report to the Council.

Blackburn.—The Gas Committee of the Town Council have now resolved to proceed with their electric lighting works. It has been decided to let the contracts immediately the minutes have been confirmed by the Council. The motive power is to be steam, and not gas, as was originally suggested.

Charge of Embezzlement.—At the Ipswich Borough Police Court, on Monday, Robert Mann, formerly manager at Ipswich for the National Telephone Company, was charged with embezzlement. It was stated that the prisoner had been in the employ of the National Telephone Company for some years, and was transferred from King's Lynn to Ipswich in February, 1892. His duties were to obtain orders and superintend the construction of telephone lines. It was no part of his duty to collect accounts, but any money tendered to him by the Company's customers should be sent on to the district manager, at Norwich. It was alleged that the prisoner received orders for the erection of telephones, but failed to account to the Company for the amounts received for the work. On being taxed with this he is alleged to have remarked that he "could not live on the income he was receiving from the Company, and the Company had better not do anything, for their own sake." Prisoner, who reserved his defence, was committed for trial at the Ipswich Sessions, which commenced yesterday.

Coleraine.—The Board of Guardians will shortly advertise for tenders for the supply and fitting of electric bells throughout the workhouse and infirmary.

Edinburgh.—A special meeting of the Edinburgh Town Council was held on Tuesday to consider an application on behalf of Messrs. Dick, Kerr and Co., the lessees of the Edinburgh street tramway undertaking, applying for the Corporation's consent to a sub-lease of that undertaking to the Edinburgh Tramways Company (Limited). After a long discussion, it was proposed and carried that the Corporation approve generally of the application from Messrs. Dick, Kerr and Co., and remit to the Lord Provost Committee for consideration as to the conditions on which the sub-lease should be granted, the Committee to report to the Council.

Fleetwood.—A public meeting of the residents has been held to receive and consider the report adopted by the Commissioners in reference to the installation of the electric light in the district. A resolution to the effect that the action taken by the Commissioners be approved was put, and carried unanimously. The recommendations of the Commissioners will be found in a recent issue of *The Electrician.*

Folkestone.—A special meeting of the Corporation was held last week to receive and consider the report of the Electric Lighting Committee. A squabble arose as to the right of trustees of the local gas company to vote on the electric lighting question, and a formal protest was entered against the ruling of the Mayor that such persons could not vote on the subject. The Electric Lighting Committee's report states that in April last they were appointed to consider and prepare a provisional scheme for the public and private lighting of Folkestone by electricity, with power to consult an expert on the subject. Acting upon this authority, Mr. Mark Parker, of Rochester, was retained to advise the Committee upon technical details. This gentleman has presented his report to the Committee, in which he describes the various systems of lighting now in operation, and their respective advantages and disadvantages. The report is accompanied by diagrams, which have materially assisted the Committee. This body are of opinion that there already exists a sufficient demand for the light to warrant the Corporation in proceeding with the erection of works, &c. They recommend that the lighting should be carried out by the Corporation, and that it would be prejudicial to the interests of the ratepayers to allow statutory powers to be granted to a private undertaking, which will probably result if the Corporation does not decide promptly in the matter. The Committee advise the adoption of the high-tension alternating-current transformer sub-station system. The report sets out the area of supply, which includes the principal thoroughfares of the town. The sum of £35,000 is estimated as the capital required, and details are given showing the estimate of cost, annual working expenses, and estimated revenue. The Committee recommend that the works be at once proceeded with under a Board of Trade licence, to be applied for forthwith, and that the services of Mr. Parker be retained, on terms to be arranged, to advise and assist the Committee and the Town Clerk in obtaining the proposed licence, in designing the necessary generating and distributing works, supervising their construction, and advising the Committee in reference to the acceptance of tenders, &c. On the motion that the report be adopted, a lengthy discussion ensued, and it was ultimately decided to adjourn the consideration of the report for three weeks, with an instruction to the Committee to ascertain what amount of current was likely to be taken by private consumers.

Galashiels.—The Town Council have considered the proposed application to the Board of Trade by the Caledonian Electric Supply Company (Limited) for authority to supply electric light within the borough of Galashiels, and, after a long discussion, have resolved to delay further consideration for another fortnight.

Heckmondwike.—The extensive electric lighting installation at the Co-operative Wholesale Society's Shoe-works has this week been brought fully into use, and is giving every satisfaction. The work has been carried out by Messrs. Ernest Scott and Mountain. There are more than 500 16-c.p. incandescents.

Inquest.—An inquest was held this week on the body of William George Taylor, who was burnt to death at the works of the British Xylonite Company, at Homerton. Mr. Curtis Hayward, B.A., the Company's solicitor, watched the case on their behalf. It was

Digitized by Google

alleged that xylonite (or celluloid) was composed of a specially manufactured tissue paper treated with nitric and sulphuric acids, and after being mixed with camphor and spirits of wine was worked into a dough, pressed into sheets, and dried. It was explained that Government experts have certified that the material is not an explosive, and as the actual manufacture was carried on in Suffolk and not in London, the works where the fire occurred (employing 300 hands) were not licensed. Mr. A. Spenser, chief officer of the Public Control Department of the London County Council, in giving evidence, stated that the room should have been lighted by electricity, as other parts of the works were, and with this precaution and Government supervision being permitted, no such accident could have happened. A verdict of "Accidental death" was returned, with a rider to the effect that no exposed lights should be allowed where the manufacture or storage in large quantities of such substances as xylonite was going on.

LANCASTER.—We are informed that the whole of the preliminary arrangements for the fitting up of the buildings and laying the mains for the public electric light installation are now almost completed, and it is anticipated that by the middle of February the Corporation will be in a position to supply current to the whole of the prescribed area.

LIVERPOOL.—*The Liverpool Mercury* thinks that now the electric light is in use in a large number of the principal business establishments in Liverpool, it is time for the Corporation to consider the question of introducing the light into the principal thoroughfares, and so to create a bulwark against the encroachments of the monopolist gas company.

MARGAM.—At a recent meeting of the Parliamentary Committee the question of the lighting of the district was discussed, and it was resolved to obtain a report from Messrs. Drake and Gorham as to the cost of lighting the district by electricity.

OSWESTRY.—At its last meeting the Town Council decided to submit objections to the Provisional Order of the local electric lighting company.

RAMSBOTTOM.—The Electric Lighting Committee of the Local Board recently held a meeting to consider a scheme for the supply of electric light to the district, and decided that, having regard to the necessity of obtaining a Provisional Order, the matter should be adjourned for further consideration, and the Committee be instructed to obtain further information on the subject.

SHOREDITCH (LONDON, E.)—The Dusting and Scavenging Committee of the Vestry have recently considered the advisability of providing a refuse destructor to deal economically with dry refuse. It appears that the barging of this refuse at present costs the Vestry nearly £7,000 per annum, and from a report received by the Electric Light Committee of the Vestry, from a leading firm of engineers, it is estimated that a saving of nearly £4,500 per annum would be effected if a refuse utiliser were provided. The Vestry have decided to take the matter into consideration. The Electric Lighting Committee have further considered the question of the proposed sight for the central lighting station, and have decided that the Pitfield-street position is the best, and recommend that the sum of £33,500 be offered therefor. The Committee's report has been adopted.

SOUTHAMPTON.—At the meeting of the Harbour Board, on Tuesday, it was reported that the two electric cranes now being fitted on the Town Quay were completed, and had stood all tests satisfactorily. The cranes are to be at once put into work. The Town Quay and offices are to be lighted by electricity.

SWANSEA.—The Sub-Committee recently appointed to report to the Local Board upon the question of electric lighting for the borough have reported that the time has now arrived when the provisions of the Swansea Electric Lighting Order, 1889, should be carried into effect. The Sub-Committee recommend that Mr. Manville be instructed to report fully upon the subject.

WESTON-SUPER-MARE.—Some time back the question of lighting the district by electricity came up for discussion, but nothing has since been done in the matter. In reply to a question at the last meeting of the Town Commissioners, the Deputy-Clerk replied that the consideration of the question had been deferred until the consultation scheme had been carried out.

WINDSOR.—At the last meeting of the Town Council correspondence was read from Messrs. C. A. Parsons and Co., and the Fowler-Waring Cables Company, in regard to negotiations which are in progress between the liquidator of the Windsor and Eton Electric Light Company (Limited), and the above-mentioned firms, with the object of making arrangements to enable the Windsor Company to resume its business in a manner satisfactory to the Council. It is proposed to put down a central station with entirely new plant, for the supply of 10,000 8-c.p. lamps, the plant to be manufactured by Messrs. Parsons and Co., and to be similar to that supplied to Scarborough, Cambridge and Newcastle-on-Tyne, the mains to be supplied by the Fowler-Waring Company, and to be similar to those supplied to the London and City of London Companies, and to the Corporations of Exeter, Brighton, &c. The system proposed is the high-tension transformer system. It is calculated that the above would involve an expenditure of £15,000, and would take six months in execution. This correspondence has been considered by the waterworks Committee of the Town Council, who have been in communication with the Board of Trade, who replied that the Provisional Order obtained by the Windsor Company had not been revoked, and did not appear to contain any provision for the transfer of its powers, duties and obligations to any company or person. The matter having been discussed, it was agreed to appoint an electric lighting committee, who will report to the Council.

WORTHING.—Preparations for the forthcoming experiments in the electrical treatment of sewage, referred to in a previous issue, are being proceeded with, and it is expected that operations will be commenced next we k. Applications for permission to be present have been received from representatives of a large number of local authorities throughout the country, as well as by many persons interested in sanitary science questions.

ANNUAL DINNER.—The annual dinner to the employés of Messrs. Laurence, Scott and Co., Gothic Works, and of the Norwich Electricity Company, was held last week, under the presidency of Mr. R. Laurence. More than ninety guests were present.

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The following report has been issued by the Directors of this Company for the half-year ended September 30th last, and will be presented to the forty-third half-yearly ordinary general meeting, to be held at Winchester House, E.C., on Thursday, the 25th inst., at one o'clock.

The revenue for the period amounted to £369,967. 5s. 1d., from which are deducted £98,106. 8s. 10d. for the ordinary expenses, and £31,906 4s. 3d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £6,753. 16s. for income tax, there remains a balance of £233,200. 16s., to which is added £1,133. 8s. 10d. brought from the preceding half-year, making a total available balance of £234,334. 4s. 10d. From this balance there have been paid—

	£	s.	d.
Interest on Debentures and Debenture Stock......	27,696	18	0
Dividend on Preference shares	20,384	12	11
Two interim dividends of 2s. 6d. per share each on the Ordinary shares	100,000	0	0
	148,081	10	11

Leaving a balance of £85,252. 13s. 11d., which is carried forward to the next account.

The revenue includes £22,373. 7s. 4d. dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

Under the terms of a contract dated June 17, 1893, with the Portuguese Government, the Brazilian Submarine Telegraph Company and this Company have secured an additional ten years of their respective privileges under existing Portuguese concessions. To obtain this extension this Company and the Brazilian Submarine Telegraph Company undertook to connect Lisbon and this Company's general system with the islands of the Azores, and the two Companies hold a large proportion of the shares in the Europe and Azores Telegraph Company, which has been formed to work the line. The new cable was laid in August last.

Since the last general meeting a cable has been laid from Zanzibar to Seychelles and Mauritius, under agreement with Her Majesty's Government and the Eastern and South African Telegraph Company, thus connecting these colonies with the Company's system of submarine telegraphs.

In accordance with the provisions of the Articles of Association, two of the Directors, Sir John Pender, G.C.M.G., M.P., and Charles W. Stronge, Esq., C.B., retire by rotation at this meeting, and, being eligible, offer themselves for re-election. The retiring auditor, Mr. Henry Dever, desires to offer his firm, Messrs. Deloitte, Dever, Griffiths and Co., for election as auditors to the Company. Messrs. Welton, Jones and Co. also retire, and offer themselves for re-election.

Anglo-American Telegraph Company (Limited).

The following is the report of the Directors of this Company to be presented at the ordinary general half-yearly meeting to be held at Winchester House, E.C., on Friday, the 26th inst. at two o'clock:—

The total receipts from July 1st to December 31, 1893, including the balance of £503. 1s. 9d. brought forward from the last account, amounted £151,095. 1s. 7d. This sum, however, is subject to revision, as the law-suit between this Company and the Paris and New York Telegraph Company is still pending before the Court of Appeal in Paris. The traffic receipts show a decrease of £8,493 as compared with the corresponding period of last year.

The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amounted to £59,250. 19s. 3d., an increase of £622. 11s. 9d.

Digitized by Google

Interim quarterly dividends of 12s. 6d. per cent. on the Ordinary stock, and £1. 5s. per cent. on the Preferred stock, were paid on November 1st last, absorbing £43,750, leaving a balance of £48,094. 2s. 4d., out of which the Directors recommend the Proprietors to declare final dividends of 13s. 6d. per cent. on the Ordinary stock, and £1. 7s. per cent. on the Preferred Stock, amounting to £47,250, making a total distribution for the year ended December 31, 1893, of £2. 11s. per cent. on the Ordinary Stock, and £5. 2s. per cent. on the Preferred Stock, leaving £844. 2s. 4d. to be carried forward to the next account.

With the exception of the Brest-St. Pierre (1869) cable, broken in April last year, and the Valentia-Heart's Content (1874) cable, broken in July, the Company's cables and land lines are in good working order and condition. The Company's s.s. "Minia" and the Telegraph Construction and Maintenance Company's s.s. "Calabria" were engaged during the summer and autumn in endeavouring to repair the two broken cables, but were unsuccessful in both cases owing to unfavourable weather.

In view of the age of the Company's cables, and the necessity for assuring the efficiency of the service, the Directors after much and anxious deliberation, have decided to lay a new cable from Ireland to Newfoundland in the coming summer. A contract has been entered into with the Telegraph Construction and Maintenance Company for the manufacture and laying of 1,955 miles of cable, between Valentia (Ireland) and Heart's Content (Newfoundland), for the sum of £450,000, which will be paid out of the renewal fund. This cable will be superior in strength and carrying capacity to any yet laid across the Atlantic.

The Directors greatly regret the loss by death, in September last, of their colleague Mr. Henry Weaver, who was connected with the Company as General Manager and Managing Director since 1870. In accordance with the Articles of Association, two Directors of the Company, Samuel Barber, Esq., and Sir Albert J. Leppoc Cappel, retire at this meeting, and, being eligible, offer themselves for re-election. Mr. Joshua Dean and Mr. John Gane, F.C.A., the auditors, retire, and offer themselves for re-election.

Direct United States Cable Company (Limited).

The following is the report of the Directors of this Company for the six months ended December 31st last, which is to be presented at the thirty-third ordinary general meeting of the Company, to be held at Winchester House, E.C., on Tuesday next, the 23rd inst., at 2 o'clock :—

The half-year's revenue, after deducting out-payments, amounted to £41,051. 19s. 11d. as compared with £43,629. 6s. 1d. for the corresponding period of 1892, being a difference of £2,577. 6s. 2d. against the half-year under review. The working and other expenses for the same period, including income-tax, amounted to £19,059. 16s. 5d., leaving a balance of £21,992. 3s. 6d. as the net profit, making with £819. 2s. 4d. brought forward from the previous half-year a total of £22,811. 5s. 10d. For the corresponding period of 1892 the working expenses and other payments amounted to £18,982. 3s. 7d.

Interim dividends of 3s. 6d. per share for the quarter ended September 30, 1893 (paid October 24, 1893), and of 3s. per share for the quarter ended December 31, 1893 (payable January 24, 1894), together amounting to £19,730. 15s., have been declared, and the balance of £3,080. 10s. 10d. on the revenue account has been carried forward.

The reconstruction of the station buildings at Ballinskelligs is being proceeded with.

The Directors announce with regret that, in consequence of failing health, Mr. Charles John Günther has resigned his seat at the Board. The casual vacancy thus created in the Board of Directors has been filled up by the election of Mr. Charles Eugene Gunther.

National Telephone Company (Limited).

An extraordinary general meeting of this Company was held yesterday (Thursday) at the Cannon-street Hotel, under the presidency of Mr. J. S. Forbes, "for the purpose of submitting a report on the progress of the Company and its business for the half-year ending October 31st last, and for considering the expediency in the future of holding half-yearly in lieu of yearly ordinary general meetings."

The SECRETARY (Mr. Albert Anns) having read the notice calling the meeting,

The CHAIRMAN in the course of his remarks said :—I want you to understand at the opening of the proceedings that this is an extraordinary general meeting, called by the Directors in order to bring before you and, so to speak, gather your opinion upon the subject referred to in the short notice convening it. The fact is that this Company, as you know, is now assuming considerable dimensions, and we believe is of some importance to the community as well as to you ; and the Directors, in existing circumstances, are rather oppressed with the responsibility when they have to carry the business on from year to year subject to the obligation, at present, of coming before you only once a year. We unanimously feel that it would be more in the interests of the Company—the shareholders, the directors, and the officers—if we had more frequent opportunities of getting into touch with each other. Every one knows that the present position of this Company is not too absolutely defined, and under any circumstances, from the very nature of it, it is not altogether an entirely smooth path. We are sufferers somewhat from a circumstance over which we have very little control—the worst circumstance possible that can affect a commercial company—the circumstance of uncertainty as to where we are. As you know, owing to the action of the Government, the position of the Company is somewhat altered. The Government came to the conclusion that the intercommunication between the great centres for telephonic purposes must be taken over by them. There was a certain Treasury Minute laying down the principles upon which that transfer of trunk wires and the future development of trunk wires by the State should be held, and we ourselves and the other telephone companies—other licensees, whoever they might be, were to be charged with the limited service in certain areas to be agreed. That was all determined in August, 1892. It was the subject of considerable negociations with the authorities of the Post Office at that time, and it was a subject of enquiry before a committee of Parliament, who reported upon it ; and upon consideration the Directors came to the conclusion that if the State insisted, there was no alternative, and that they must make the best of it by agreeing to terms that would leave them in that position. Within the area of the licence as amended they were to carry on the telephone business—the local business, so to say. The State was to provide the communication in the nature of trunk wires in all the great centres, and we were to co-operate with the Post Office in carrying on with efficiency, and as economically as circumstances justified, the telephonic communication, both local and through. That has been pending a long time. As a condition of that agreement, of course, the moment it appeared the State assumed the duty of furnishing what we called trunk connections between the great centres, and it was useless for us to spend any more money on those connections outside the areas which, under the revised licence, we should be charged with the work of, and we were called upon by the Post Office to abstain from further work in the direction of trunk wires, the condition of the bargain being that those wires which we have already, at a considerable expenditure of capital, constructed between these centres, are to be transferred to the Postmaster-General on payment of their book cost, with a small addition to cover the cost of administration and so forth. We therefore suspended any further capital expenditure in that direction, naturally. However, the thing goes on. The Post Office, no doubt, are engaged at the present time in the construction of certain great arterial lines, but in many portions of the country where intercommunication between towns requires some expansion to carry on the trunk messages between those towns—for instance, Manchester and Liverpool, and Liverpool and Leeds—we are now beginning to suffer rather seriously from the want of more communications of that sort. In the meantime there has been a change of Government, and the agreement subsisting between the Government and the Company is in a state of suspense—at all events, it has not progressed very rapidly. It was rather complicated and not very simple or easy to enlarge, although the heads of agreement are contained upon a sheet of foolscap. When you come, with the assistance of your technical friends and of your legal friends—Sir Robert Hunter on the one side, and Mr. Crisp on the other side—there are certain words which have a pregnant meaning as to where the parties differ—some questions of principle which, when you tackle the details, involve necessarily a good deal of discussion and some differences of opinion, and it all has at last, by compromise or agreement, to be got into what is called a legal form. That has been going on. Meantime one of the conditions upon which we entered into this agreement has been somewhat altered. We assumed when the Postmaster-General, duly authorised by the Government, put his initials to the heads of agreement that that was the agreement, and those heads of agreement we are prepared to carry out loyally and efficiently. Meantime, however, Parliament has had some discussion on the subject, and the Government, I daresay actuated by the best motives, have pledged themselves that our agreement shall not be completed until it has been submitted to Parliament. Every one knows that during the last two months Parliament has been occupied upon matters even more vital to the community than the efficiency of telephonic communication, and our agreement is not through ; but I will tell you what is going on all this while if the agreement flags. Our business is obstructed, and the general convenience is being neglected, and that is one illustration of the kind of reason which has induced the Board to say, We are like an ordinary individual charged with a great responsibility. He sometimes finds that he cannot carry it all, and then he takes counsel of his friends, and that is the underlying thought and principle which has brought us together to-day. In these great and complicated businesses, with hundreds of centres, the necessities of the thing require an enormous mass of detail—the accounting, the letter-writing, the necessary exchange of correspondence and documents, and all that sort of thing—involving enormous machinery and great labour. As our company was constituted we came into existence on a particular day of the year—unhappily not on the 1st of January, but the 1st of May ; so when you talk of a telephonic year, the times are out of joint. One gets fairly puzzled as to whether it was 1892 or 1893 that one was talking about. I am now going to talk about a year which is partly 1893 and partly 1894. It is a great inconvenience, and we think it quite worth our while to get rid of it. There is another reason why we should do so. Most of the great commercial companies have a yearly account based on the calendar year, and what we propose to recommend, if you see no great objection to it, is the adoption of a similar course. We have had the accounts prepared for the half-year ended October 31st, and although, I believe, we have not received the official approval of the auditors, you may take it that the figures I shall present to you are duly authenticated, and they are useful as showing where the Company has got to in the interval of six months since we dealt with the year's accounts. Generally, you remember what took place at the last meeting. You remember our absorption of the other companies, and one of our conditions with the Post Office in the agreement I referred to is that we should procure the surrender by those companies of all the country licences, because our licence now is one restricting us to certain limited areas. Last year we had made considerable progress after long and difficult negotiation, in getting all those companies into the fold, and our capital up to the end of that year represented not only the cost of the original three companies amalgamated under the term "National," but of a number of companies brought in. The Irish Company, however, was then outside, but that, too, is now in ; and I believe that as far as we are concerned that is an end of the affair. The purchase of this company will account for one of the principal items of

Digitized by Google

the expenditure of capital in the half-year. Then, it has always been necessary for us, and I am afraid it always will be, to add to our capital expenditure for the expansion of our business. Those are the only two additions to our capital; and without referring to the figures, I may say that the capital expenditure has been in round figures about £121,000 on the purchase of the Irish Company, and about £90,000 upon the expansion of our business. Then, what is the result of the working of the undertaking? Upon the last year, without the Irish Company, we found ourselves in this position—that after paying the working expenses, and the enormous royalty to the Post Office, we were enabled to clear the interest on our debentures, to pay the interest on our first and second preferences, which amount to £150,000 each, and bear 6 per cent.; we were also able to pay 5 per cent. on nearly £600,000 of third preference shares, and with the almost universal assent of our proprietors, we paid 5 per cent. on the Ordinary capital, carrying a considerable balance to reserve. It was thought wise in our circumstances, the Company having a constant pressure on it for making extensions, and with our short "life," to adhere to the sound principle of paying a moderate dividend and carrying a large sum to reserve, so that we might be armed in the furure against contingencies. Applying this to the business of the past half year, notwithstanding that our capital account has increased by the purchase of the Irish Company and our additional outlay in extending our business, we shall be able to maintain the same position and carry forward a considerable margin into the current half-year. When we come to the end of our year—April 30th—we have no reason to doubt that our position will be the maintenance of these payments upon our debentures and our several stocks, and to carry forward a considerable margin to our reserve. We had intended to present the half-year's accounts to you as you came into the room, but upon reflection we thought that that might be open to the suggestion that a certain number of shareholders would have the figures in their possession before the general body of the shareholders. We therefore decided that it would be fairer to send the accounts out with the report of these proceedings as early as possible after the meeting. Our business is progressing, notwithstanding the considerable drawbacks attending the state of uncertainty in which we are placed, and I trust that it has also increased in efficiency. There is no doubt that there were (and, I dare say are) grounds of complaint, but we are not only devoting enormous time and skill, but are also spending a very large sum of money on the concern. If people will take the trouble to compare like with like, I will venture to affirm—backed with all the knowledge and experience of my colleagues, who are practical working men, and some of them skilled electricians—that we are now doing this service in our chief centres as efficiently and as cheaply as it is being done in any place in the world. In order that that statement may be contradicted I invite a challenge from anyone interested. There is an illusion that our subscription in London is £20, but it is really £15. We have in London an enormous number of subscribers—over 10,000—and the average payment is £15, of which an equivalent number of shillings goes into the pockets of the Post Office. The wayleaves in London are not only extremely costly, but in consequence of the nature of our occupation are extremely complicated and multiplied. We have no power to do, in a legal and in the most efficient mechanical way, what the service requires, and we are obliged to go by roundabout and costly methods. That is not the case in Stockholm; all this is done there by the Government, who do exactly what they please. In Paris, too, it is done by the Government, who do not pay anything excessive for wayleaves. All these things ought to be remembered in connection with the cost of our work and the way in which it is done. If our Company were placed in the position that it ought to be in, and which two separate Committees of Parliament have said we ought to be in—that is, armed with power to erect their wires so that the most efficient service could be given to the public—your working expenses would be enormously less, and the subscription would probably fall in a relative degree. The resolution I shall propose is:—

"*That in future two ordinary general meetings be held in each year, and that the Directors be requested to take the necessary steps to have the Articles of Association of the Company altered accordingly.*"

The rider to that will be that those two meetings shall be so arranged as to fit in with the natural year. We have just paid six months' interest to October 31st. Our ordinary year ends on April 30th. In the ordinary course, about the early part of July we shall meet you and distribute the balance for the year. What we should propose to do, with your approval, would be to defer the payment of next half-year's interest until we closed the accounts up to June 30th, and probably we should declare a dividend at the meeting in July up to June 30th, which would, in fact, be eight months' dividend instead of six months. Subsequently we should fall into a regular state of things.

Lord BALFOUR OF BURLEIGH, in seconding the motion, reiterated the Chairman's statement regarding the unanimity of the Board in their desire to hold half-yearly instead of yearly meetings.

The CHAIRMAN, in reply to some remarks from a shareholder, stated that there was no doubt they must have a very large reserve fund, but whether it was essential that it should be invested in the business or in securities apart from the business was a matter which they could determine when they approached the question nearer than they had done up to the present time. He might state that the reserve fund had increased, and it now amounted to £161,401, which might have been distributed among the shareholders, but for prudential motives. There was no necessity for anyone to be alarmed about the Company only having a short "life," but it was necessary on that account to increase their savings. Their tenure was 18 years from January 1st, but the State might resume possession before the end of that period. If the Government under their powers gave them notice in 1897, they would take possession on arbitration terms, but he did not know they would pay the market price. The Directors had considered the question of putting the reserve into investments, but they had not yet arrived at any decision on the point, although they might do so at their next meeting. In answer to a further question, the Chairman stated that the agreement with the Post Office had to be submitted to the House of Commons, but if it was dealt with by that assembly in a manner detrimental to them they would reserve their right of re-entry. The fact that there was no agreement, however, placed the Company and the users of the telephone "between the devil and the deep sea"; and every month the Company were deprived of the benefits of their enterprise, and were prevented from adding to the efficiency of the service.

The motion was then adopted unanimously, and a vote of thanks to the Chairman and Directors closed the meeting.

Fowler-Waring Cables Company (Limited).

The fifth ordinary general meeting of the Fowler-Waring Cables Company (Limited) was held at the offices, Victoria Mansions, 32, Victoria-street, Westmister, London, on the 12th inst., Mr. William Fowler presiding.

The SECRETARY (Mr. D. Stephen) having read the notice calling the meeting as above,

The CHAIRMAN said: The motion that I have to propose is, "That the report and accounts, as distributed, be received and adopted," and in moving that, I have to make a few remarks. Like everyone else, I greatly regret that we are not able to pay a dividend this year, more especially as we have not paid a dividend since the formation of the Company. This has been a cause of great regret to us all, but I should observe that we, as Directors, have on this occasion, as you see by the accounts, waived all our fees, both for the past and the present year, and, therefore, we have shown our disposition to assist the Company, financially and otherwise, in every possible way. The real cause of the want of dividend, I think, may be stated to be the general depression of business in 1893—in all business, including electrical business—and the great competition which there has been in the electrical business itself especially. That I think everyone who knows anything about the matter will know to be a correct statement. The general condition is so fully set forth in the report that I do not think I need enter into details. The balance-sheet is very carefully drawn up, and everything, I may say, has been taken with the intention of showing the shareholders exactly how the matter stands, and we have not shown a profit that was not actually made. In fact, we might have shown a much larger profit had we chosen to value things beyond what is correct in a business point of view. We have taken great care not to do that, but to show only the real, genuine profit made. I only regret, as I said before, that it has not been larger. All that we want, with our admirable factory and admirable machinery of every kind, is a larger amount of orders, and I think we may hope that the year now begun will be a better year than the last. There is one other point I must refer to, and it is not a pleasant one, but we have mentioned it in the report—that is, that we do still require additional working capital. We are endeavouring to raise that in a way that I hope will be satisfactory, but if we do not succeed in that, we may have to appeal to the shareholders for their help in the matter. So far we have obtained no such help from the shareholders, but I hope, if it is absolutely necessary to appeal to them, that they will come to our assistance. I trust, however, that that will not be necessary. I do not think if I made a very long speech I could say more than I have done, but I should like to add one word. I do think that the management of our Company, speaking generally, has been extremely able, and all that we could desire. My impression is that if we were to appoint a hundred men we could not get a better man than we have already, and I feel every year additional confidence in his management of the Company, in his energy, his industry, and his ability, and I think you will all agree that no Company of this sort can succeed unless the management be of the right kind. One might say that with such management we ought surely to have obtained a better result; but I have already mentioned the reasons why I believe we have not done so. However, I have great hope that with this management we shall yet make this a successful Company. That is all I have to say, but if any shareholder present likes to ask me any question I shall be happy to reply.

Mr. FLETCHER said he had attended the meeting on purpose to express, on behalf of the shareholders as well as on his own behalf, their deep thanks to the Board for the way they had met the position of the Company, and the example they had shown to Directors generally, in giving up their fees and in also meeting the difficulties of the Company by advancing it money. He wished that other Directors had done their duty half as well in other companies in which he had been concerned. Reference had been made to the depression in trade. He did not know anything about the electrical trade; but wherever one went nowadays in England and abroad, one saw everything connected with the laying of cables. He had rather expected to hear some sort of explanation as to their own want of success in the face of this enormous increase in the use of electrical cables. It seemed to an ordinary outsider (and he only spoke from an outsider's point of view) that there never was so busy a time for electrical working and the laying of new mains. He had been wondering whether the Fowler-Waring cable was the best for the purpose, or whether it was being superseded by other mains for transmitting current. If that were so would it not be better at once to wipe off from the credit side of the balance-sheet the item "by patents and goodwill," £41,000? It was only a paper asset at any time, and I think it would be an encouragement to the Directors if this item were written off. It was a matter that could be done in a few days and at no expense, and he thought it would be more satisfactory to the Directors themselves to do so, as they would then have less capital to pay on, and they would thus show better results. The shareholders had no idea as to

Digitized by Google

what the turnover of the Company was, and it was impossible for them therefore to judge in any way what capital they required and why it was required. Certainly things looked improving now. There were two ways of meeting the depression. One was to concentrate their works, and the other was to increase them, and the general idea in the last ten years had always been to increase them, and to say that if there was more work there would be more profit. The result of this view, however, had been that trading in this country had been eminently unsatisfactory in the past ten years.

The CHAIRMAN: I will ask Mr. Mavor to say a few words with regard to the question of depression in electrical and other business. I have no doubt that what you say is perfectly correct, that there is great activity in the electrical industry; but Mr. Mavor can inform us whether in 1893 there has been depression in electrical works even, as in all other kinds of business. As to our turnover, we do not generally publish particulars, but we should be very glad to tell you privately after the meeting the actual amount of our turnover in each year. There is no doubt that the turnover last year was considerably greater than it was in the year before, and that is satisfactory as far as it goes. The profit was not so large proportionately, the reason being that owing to competition the estimates had to be made on a somewhat less profitable scale than in former years. With respect to reducing the capital, that is, apparently, an easy matter, but we should have to go to the Court, and I believe that you would have to put the words "and reduced" after the name of your Company. For a certain period that would have to be done, and I think that would be very objectionable, although it has often been done. Still, I do not like it, and I should not care to have my name associated with such a proceeding. That may be partly a question of feeling, but I think that such a proceeding would tend to reflect on the credit of the Company. You spoke about concentrating, and making the business more profitable with the existing capital. You must remember that the real difficulty is this—that the fixed charges of a business remain very much the same whatever the amount of the business is. If you do a large business the profit is far greater in proportion than if you do a small business, but doing a large business requires more actual money in hand. I think that that is the explanation of the point you refer to about our requiring more capital. In order to make the business pay we must have a larger turnover in proportion to the fixed charges of the business. That is the case with all manufacturers, unless we can obtain a small number of orders at a very large profit. In that case we can do with a small capital. The trouble is that the tendency in modern times in everything is to have work done at a less rate of profit, and in a finer way, as regards profit and loss, than in former times. I am therefore afraid that there would be some difficulty in our doing what you desire in that respect, although no one would be more desirous of doing it than the Directors. We should greatly like to do a small business at a very large profit, but I do not think that in these days that is easy of accomplishment. I will now ask Mr. Mavor to tell us in a few words what he feels regarding the subject of depression in electrical matters in 1893.

Mr. FLETCHER said he had rather referred to the reduction of capital as a suggestion for the Directors' consideration than advocating it himself.

Mr. MAVOR stated that with respect to the state of electrical enterprise in England in 1893, it would be utterly impossible in a few words to give a detailed explanation, and fully amplify the statement that it was depressed, but it was very easy for him to give evidence to that effect, because on the previous night the President of the Institution of Electrical Engineers delivered his Inaugural Address, and sketched the progress of electrical enterprise since 1882, when the Electric Lighting Act was passed, and clearly showed how electrical enterprise in England had been kept back, having been severely hampered by a great many causes, but mainly by legislative difficulties. The business was active in the later months of 1893, and the shareholder was quite correct in saying that at present every one saw streets being opened up and mains laid; and it might be consoling to him to know that this Company have a large share of this work in London and other places. As to whether their cables maintained their position, they were at least as good as any and better than many. He would not say that theirs were the only good cables, but trials had demonstrated clearly that the Company were in the front rank as cable manufacturers. As to the asset of £41,000 for "patents and goodwill," which has been pointed to, he did not think that that amount would appear so large when the Company's position was reviewed at a later stage of its history. They were thoroughly in a position to compete with the greatest of their rivals, and so far as they had gone, they have really equalled the best of the work that had been done.

Mr. FLETCHER said he was much obliged to Mr. Mavor for his statement.

The CHAIRMAN: I may add, in answer to what was said about our cables holding their own, that the fact that we have had a large increase in our turnover this year shows that we hold our own.

Mr. FLETCHER assented, and added, that with an increased turnover now and with practically everything wiped off, the prospect of having a dividend next year looked satisfactory.

The CHAIRMAN: I can make no promise, but I have great hopes.

Lord MEDWAY then seconded the adoption of the report, which was unanimously agreed to.

The CHAIRMAN then proposed "That Lord Medway and Mr. Smart, the retiring Directors, be re-elected."

Mr. GEORGE FLEMING seconded the motion, which was adopted, and Messrs. Cooper Bros. were afterwards re-elected as Auditors.

On the motion of Mr. FLETCHER a vote of thanks was passed to the Chairman.

The CHAIRMAN: I thank you very much. I wish I could have placed some more agreeable statement before you.

The meeting then separated.

NEW COMPANIES, STATUTORY RETURNS, &c.

KERBEY BOWEN (LIMITED).—This Company was registered on January 16th with a capital of £20,000, in £10 shares, to carry into effect an agreement between Mr. Kerbey D. Bowen, electrical engineer, and Nathaniel Hemming, to carry on business as builders and manufacturers of and dealers in launches, yachts, ships, and boats of all kinds, to be propelled by electricity, steam, or other power, and also as electricians, iron and brass founders, engineers, and manufacturers of machinery, tools, and implements of every description, and to erect, construct, lay down, enlarge, alter and maintain any buildings, charging stations, works, and machinery necessary or convenient for the Company's business. The subscribers with one share each are: K. D. Bowen, J. Strick, L. H. Grundy, H. V. Reader, W. Sidley, Mrs. E. Bowen, T. M. Colson.

ANDER'S TELEPHONE COMPANY (LIMITED).—By an agreement, dated November 25, 1893 (filed December 5th following), the Company acquires from George L. Anders and Walther Kottgen the patents Nos. 1,637, 5,712, 12,528, and 20,610, of 1892, relating to improvements in telephonic apparatus, and in consideration therefor agrees to allot as fully paid 750 shares, of £1 each, to George L. Anders, and 2,250 shares to Walther Kottgen.

BOURNE AND GRANT ELECTRICITY SUPPLY COMPANY (LIMITED).—The statutory return of this Company, made up to September 25, 1893, has just been filed. The nominal capital is £25,000, divided into 24,900 Ordinary and 100 Founders' shares, of £1 each. 18,207 Ordinary and 100 Founders' shares have been taken up, and a call of 10s. upon each share made. The calls paid have realised £9,078. 10s., while £75 remains unpaid. By special resolution, passed December 18, 1893, and confirmed January 3, 1894, the nominal capital was increased to £45,000 by the creation of 20,000 new Ordinary shares of £1 each.

BRITISH VOLTA ELECTRIC GLOW LAMP COMPANY (LIMITED).—This Company, on December 19, 1893, entered into an agreement with William Habgood and Edwin C. Lacey for the acquisition of provisional patent No. 16,514, of 1893, for "Improvements in electric incandescent lamps," and agreed to allot 300 fully-paid shares to William Habgood and 100 similar shares to Edwin C. Lacey as a purchase consideration.

CITY NOTES, &c.

CENTRAL AND SOUTH AMERICAN TELEGRAPH COMPANY.—This Company has declared a quarterly dividend of $1\frac{1}{4}$ per cent., which was payable on January 10th. The quarter's working showed a surplus above dividend requirements of $28,248, making with receipts from other sources, including the Guatemala subsidy, a total surplus of $194,157. Deducting expenses for improvements, including the cost of the Guatemala cable connection, there was a surplus of $159,223, which, added to the surplus on September 30th, made a total at the end of the year of $537,554.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The accounts of this Company for the past half-year show a balance, after providing for the debenture interest and the full dividend on the 5 per cent. Preference shares, sufficient to allow the payment of a dividend on the Consolidated Ordinary Stock at the rate of $\frac{5}{8}$ per cent. per annum, against a dividend at the same rate for the corresponding period last year, leaving £1,064 to be carried forward, as against £822 for the same period last year.—The traffic returns of this Company for the week ended January 14th, were £951, as against £1,008 for the corresponding period of last year, being a decrease of £57. The total receipts for the half-year amount to £1,941, as against £2,006 for the corresponding period of 1893, a decrease of £65.

CHATHAM, ROCHESTER, & DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED),—A prospectus is issued inviting applications for £4,000 5 per cent. 1st mortgage debentures in this Company (forming part of £12,000 authorised). The subscriptions are £10 on application, £15 on allotment, and £75 within 14 days after allotment.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company notify that the Coupons on the Five per cent. Debentures due February 1st will be paid on and after that date by Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

MEXICAN TELEGRAPH (CABLE) COMPANY.—This Company has declared a quarterly dividend of $2\frac{1}{2}$ per cent., which was payable on January 17th. The quarter's operations showed a surplus of $19,000, but repairs and renewals required $21,400, leaving a deficit of $2,400. As, however, a surplus of $366,261 was brought in, the year closed with an accumulated surplus of $363,837.

PORT BEIRA PIER, TRAMWAY, AND TELEGRAPH COMPANY (LIMITED).
It is announced that letters of allotment in this Company's recent application for subscriptions have been posted.

MESSRS. ROBEY AND CO. (LIMITED).—A prospectus has appeared this week inviting subscriptions for £125,000 $4\frac{1}{2}$ per cent. registered first mortgage debentures in the above Company, secured by a first mortgage on the freehold engineering works of the Company at Lincoln, and also forming a floating charge on all other property of the Company. The prospectus states that this issue is made in consequence of the deaths of partners, and with a view of facilitating family arrangements. The present management is to remain unchanged. The debentures may be redeemed by the Company any time after January 1, 1914, at £105. The subscription list closes to-day (Friday), at 4 o'clock. £5 per debenture is payable on application, £25 on allotment, and £70 on March 31st next.

Digitized by Google

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY.—The Directors of this Company recommend the payment of a dividend of 4½ per cent. for the year ended December 31st last. The transfer books of the Company will be closed from the 20th inst. to Feubrary 5th.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ending January 12th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,297.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 819.—Vol. XXXII. FRIDAY, JANUARY 26, 1894. PRICE SIXPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The most sensational experiment at the Royal Institution on Friday last was the freezing of air into solid transparent ice. Prof. Dewar has not yet succeeded in solidifying oxygen, and until further improvements are made in the process, neither feat seems worth the expense; for the scientific value of the experiment seems small compared with the many other researches which have been carried out at very low temperatures. Prof. Dewar is so very reluctant to publish any authoritative account of his work, that it is not surprising if it is sometimes misrepresented. The opaque vacuum fallacy was started in *The Times* just a year ago, in an account of a lecture by Prof. Dewar, was countenanced by technical journals (important and otherwise), and deceived many readers, among whom was Mr. Tesla; but, as far as we know, was never disclaimed by Prof. Dewar in print. *The Times* on Monday last dwelt at some length on vacuum and liquid oxygen jackets to show that it is now quite orthodox, but the *Daily Chronicle* could hardly be expected to give three-quarters of a column to a scientific subject without an ambiguity, if not an amusing mistake. The latent fallacy appears, moreover, in an apparently verbatim report. Electric discharges were sent through exhausted globes, "but all the well-known phenomena of phosphorescence ceased as soon as intense cold was applied, the electricity tried to pass by any route rather than through the globe. 'What did this mean?' said the professor. 'Obviously that something was now frozen out which had before enabled the electricity to pass across the vacuous space.'" Everyone who has even casually perused Prof. Crookes' writings is familiar with the fact that the luminosity of vacuum tubes begins to fall when lower pressures than about one millionth are reached, and that non-conducting vacua are obtained without difficulty; but a timely word from Prof. Dewar would stop the propagation of the idea that the ether was frozen out. Now the general public, and those who write for them in the daily papers, are sufficiently familiar with the ether to discourse pleasantly about it, Dr. Oliver Lodge writes in a contemporary that at the temperature of absolute zero the molecules of a perfect gas "would be lying all about the floor in an inert and stationary condition, and could be swept up." It is rather dangerous to let the public hear such things. We shall hear one fine day that Prof. Dewar handed round lumps of frozen ether on a plate.

The six sections of Mr. Preece's "Notes of a Trip to the United States and to Chicago, 1893," which were read before the Institution of Electrical Engineers last night, are of more technical interest and importance than one might at first be led to expect from a glance at the title. Meanwhile, we may remark that the bulk of the communication by Mr. Preece consists of a careful and expert analysis of the telegraph system of the United States, appended to which we have sections on American telephones, electric lighting, and electric railways, and Mr. Preece's views on the so called "World's Fair" and the Electrical Congress at Chicago. One of the most instructive features of the Paper is the series of comparisons which is drawn between the details of American and British practice, to the advantage on the whole of the practice on this side of the Atlantic. "Our apparatus is better," says Mr. Preece, in his criticisms of American telegraphy, "our speed is higher. Messages are handled with greater reliability." This may be taken as the keynote of the Paper, which will be published in our next issue.

In a recent communication to the Royal Society, Mr. E. H. Griffiths has submitted a corrected value of Joule's mechanical equivalent of heat. In his original Paper, about a year ago, the author stated that a careful comparison of thermometers would be made. This comparison has been completed, and he announces that the corrected value of J in terms of a thermal unit at 15°C. is given as $4{\cdot}1982 \times 10^7$ ergs, with an estimated limit of error equal to $\pm$ 0·0020. Hence, assuming that $g = 981{\cdot}17$ cms. per second per second, the mechanical equivalent of one British thermal unit is equal to 779·77 ft. lbs. If there is one thing more remarkable than another about the successive determinations of J which have been made from time to time, it is the alarming rate at which the value is rising above the original 772·55.

Although some of the rules for the insulation of house-wiring are expressed in terms of the leakage current, it is a mistake to suppose that the leakage current is in itself a matter of importance. The leakage current allowed by the rules of the Institution of Electrical Engineers—$\frac{1}{5000}$ of the whole current—would, as we have already observed, be too small to do any harm; but the quality of the insulation which would allow such a current to pass is not good enough to satisfy most engineers. Our correspondent, who suggests that the standard for alternating work should be about 1·4

Digitized by Google

times higher than for continuous-current supply, seems to consider the leakage current rather than the quality of the materials and work. Higher insulation has been demanded for alternate-current work probably on account of a vague idea that this system is associated with high voltage, that it is rather mysterious, and that double precautions had better be taken. We are inclined, to think on the contrary, that lower insulation might be used. The only harm of a leakage current, namely, electrolysis, would probably be less with an alternating than with a direct current, and where house transformers are used, the insulation of a single house is alone concerned, and not the insulation of the supply company's mains. One of the greatest advantages of alternate-current supply seems to be, or rather to have been, this isolation of each separate secondary circuit, and the impossibility of interference with one circuit by the presence of a leak on another. We say that this was an advantage, for now that sub-stations and low pressure networks are becoming fashionable, this feature disappears, and there remain the advantages that secondary batteries and motors cannot be used; but about these there is some doubt.

In spite of the steadily-increasing economy with which the City and South London Railway is worked, both in the gross and in the matter of locomotive and generating expenses, it continues to pay a dividend of microscopic proportions, and it is pretty evident that it is to the extensions, north and south, that the ordinary shareholders must look for a more substantial return. Since the opening of the line some three years ago nearly 17½ million passengers have been carried, and about £128,000 have been earned, the returns for the last half-year showing, under both these headings, that the stationary stage has been reached, although the train mileage continues to grow, and now stands at 224,101 for the six months ended December 31st last. The figures below, exhibiting, as they do, a steady improvement, serve to show the monetary value of experience; but, unfortunately, engineering economies alone will not make a fat dividend any more than one swallow will make a summer:—

—	Train mileage.	"Loco." and generating expenses.	Ditto per mile run.
Half-year ending June 30, 1891...	174.435	£6.587	9·0d.
" " Dec. 31, 1891...	188.666	6,199	7·9d.
" " June 30, 1892...	188,944	6,035	7·6d.
" " Dec. 31, 1892...	234.417	6.348	7·1d.
" " June 30, 1893...	217,664	5,876	6·5d.
" " Dec. 31, 1893...	224,101	5,814	6·2d.

Similar causes do not always give rise to identical effects. During the recent coal crisis, the fuel at one of the London electric supply stations began to run short, and a few tons of coal to which the stokers were unaccustomed was brought in, hurriedly thrown on the stoking floor, and used on all the boilers under steam in the station. As dusk came on nearly all the fires clinkered, steam began to fall, and nothing could be done but to draw the fires, clean the bars, and rely on the batteries. As the load rose, thousands of amperes were discharged, the cells stood the strain bravely, but the fires were not made again until the volts had begun to follow the steam pressure. Next morning the secretary was inundated with letters; each consumer complained that something had been wrong with "his" electric light, it had "gone dim last night," and begged that some one might be sent round "to see to it." It speaks well for the service that hitches of this kind were absolutely unknown in this district, and caused so much agitation. The converse case occurred a few days ago. The owner of a new and admirably decorated house was showing some friends over it, turning on the electric lights as he passed from room to room, and forgetting to turn them off again. The main fuse, by extreme carelessness of the contractors, was a makeshift affair, "went," and left the house in utter darkness. Never thinking that there could be anything wrong, since an insulation of millions of ohms had been declared only a few days earlier, he at once concluded that some disaster had befallen the supply station. His son was despatched at once, with instructions to beg that if all the machinery were not wrecked, some electric light might be sent to —— Gardens. One of the staff obligingly came to the rescue, and put matters right within an hour or so.

Tunbridge Wells.—The Local Government Board has sanctioned the application made by the Corporation to spend £13,000 on electric lighting.

Electric Traction in Japan.—A concession has been secured by an American for the construction of an electric railway between Tokyo and Yokohama, a distance of about 17 miles.

The Heilmann Locomotive.—This locomotive has been tried on the railway between Havre and Paris. It was attached to a train of 13 carriages, and attained, it is said, a speed of 75 miles an hour.

Meter Inspectors.—The Paisley Town Council are proposing that the gas meter inspectors should wear a distinctive badge. It was suggested that they should wander about with an oil lamp in their hand seeking for an accurately-registering meter.

The Cost of Lighting the City.—An account of the estimated assets and liabilities of the Commissioners of Sewers of the City of London has just been published. The liabilities amount to £383,362, including electric lighting, £18,332; gas lighting and testing, £7,500.

Electrical Trade Section.—A meeting of the Electrical Trade Section will be held at Botolph House, Eastcheap, on Monday next, at 3 p.m., to consider, amongst other things, the report of the Traction Committee, and the appointment of a Parliamentary Committee.

Gutta-Percha.—The Société d'Encouragement pour l'Industrie Nationale is offering a prize of £120 to anyone who will devise a substance capable of completely replacing gutta-percha in one at least of its principal uses, or for a work contributing to the increased production and better exploitation of this gum.

The Telegraph on the Congo.—The Congo Company contemplate the building of a telegraph line from Boma, over Matadi, Leopoldville, and Stanley Falls to the Tanganyika Lake. The total distance is about 4,800 miles, and the completion of the whole line will occupy several years. The Boma-Kenge section is expected to be finished during 1894-95.

A New French Cable.—A new French submarine cable is about to be laid in the Red Sea, crossing the bay of Jibuteel, and placing Obock in communication with Jibuteel, which is to be the new seat of government of the French colony. The cable is 31½ nautical miles in length, and is to be laid by the telegraph ship "La Charente."

Digitized by Google

Central London Railway.—The Examiner on Standing Orders of the House of Commons has found that the standing orders had not been complied with in the case of the Bill for the extension of time of the Central London Electric Railway, on the ground that no proof had been adduced of service of notice upon certain owners, lessees, and occupiers of property in the parish of Holbo:n above Bars.

Newport.—At a meeting of the Parliamentary and Improvement Committee of the Corporation, on Tuesday last, the question of lighting the town by electricity was again taken into consideration. After a protracted discussion nothing definite was arrived at, but the members of the committee agreed to accept an offer made by Messrs Crompton to inspect their works at Chelmsford before deciding upon a tender.

Candles v. Electricity on Coastguard Ships.—The *Broad Arrow* is responsible for the statement that orders have been issued to the coastguard ships which are fitted with the electric light that candles are to be used upon all occasions when not under weigh. From a calculation which has been made in one ship, it appears that the cost of lighting by the electric light per day is 5s., and by candles 4s. 8d.

A Journal of Elementary Mathematics.—At the twentieth meeting of the Association for the Improvement of Geometrical Teaching, held at University College on the 13th inst., the following resolution was passed unanimously :—"That a terminal Journal of Elementary Mathematics be published by the Association; that it be entitled *The Mathematical Gazette*, a terminal journal for students and teachers; that it be edited by Mr. E. M. Langley."

Football by Electric Light.—A peculiar question will, it is said, probably come before the Scottish Football Association at its next meeting. With the object of playing night matches the Celtic Club introduced the electric light on to their field, and during a match the other week the ball came in contact with the wires several times. Protests were lodged, but eventually withdrawn, though the question is to be brought before the notice of the authorities.

Cable Interruptions and Repairs:

	Date of Interruption.	Date of Repair.
Bonny-Cameroons	Jan. 15th, 1894	Jan. 18, 1894
Foochow-Shanghai	Jan. 15th, 1894	Jan. 19, 1894
Penang-Medan	Jan. 14th, 1894	Jan. 24, 1894
Cayenne-Paramaribo	Oct. 15th, 1893	—
Cayenne-Vizeu	Nov. 25th, 1893	—
Haiphong-Hongkong	Dec. 11th, 1893	—
Garachico-Santa Cruz de Palma	Dec. 27th, 1893	—

The Ludgate Hill Explosions.—At the last meeting of the City Commissioners of Sewers, Mr. Ross, in the absence of the engineer, read a report from Mr. W. H. Preece on the subject of the recent explosions on Ludgate-hill. Mr. Preece stated that the explosions were due to a collection of coal-gas and air in the boxes, but the cause of ignition was not apparent. Since the occurrence the City Company had introduced a system of inspection of such boxes so as to prevent a collection of gas from leaky mains in them.

A 10,000-Light Westinghouse Alternator.—The Westinghouse Company have recently built four new alternating-current dynamos for the Louisville Gas Company. The armatures are 12ft. in diameter, and the number of poles is 80. This allows the dynamos to be run at 90 revolutions. Each machine has a capacity of 10,000 lamps and weighs 50 tons. A notable feature is the economy of floor space in connection with the large output; but considerable head-room will be required, as the dynamos are 20ft. high. These alternators are designed to be directly coupled to engines.

The Cost of Lighting Paris.—According to the estimates just published, the cost of lighting Paris during the current year will be as follows:—Price of gas, 4,075,511fr.; maintenance of gas apparatus, lamps, &c., 1,166,400fr.; lighting the markets, abattoirs, &c., 101,500fr.; for oil and the maintenance of oil lighting apparatus, 70,400fr.; electric lighting of streets, 507,453fr.; electric lighting in markets, abattoirs, and others places appertaining to the Municipality, 587,000fr.; maintenance of the municipal electric lighting station at the Halles Centrales, 456,400fr., or in all about 7,000,000fr.

Northern Society of Electrical Engineers.—The Inaugural dinner of the Society was held at the Palatine Hotel, Manchester, on Monday last. In the unavoidable absence of the President (Dr. John Hopkinson), Mr. Henry Edmunds, one of the Vice-Presidents, occupied the chair. He was supported by Messrs. G. E. Preece, and W. P. J. Fawcus, Vice-Presidents and the following members of Council: Dr. Edward Hopkinson, Messrs. J. Vincent Swindells, A. Eckstein, G. W. Lowcock, E. A. Claremint, Alex. Marr, J. H. Rider, J. Taylor, C. S. Northcote, Mr. Geo. J. Somerville, Hon. Treasurer, Mr. John Darney, Hon. Secretary, and upwards of 50 members.

Prof. Minchin's Sensitive Cells and the Light of the Stars.—In a letter to *Nature* of January 18th, Prof. Minchin describes some results obtained by him at Daramona House, Westmeath, by aid of Mr. W. E. Wilson's two-feet reflector in measuring the photo-electric effect of the light of the planets and fixed stars. The sensitive cells employed were seleno-aluminium-aenanthol cells, three square millimetres in area, and were connected with the telescope in place of the eye-piece. Clifton's form of the quadrant electrometer was employed. An electromotive force of 1 volt was represented by 460 scale divisions. Venus (quarter of disc) gave 40 divisions; Sirius, 9 divisions. Aldebaran gave no result.

Long-Distance Telephony.—At the conclusion of a mathematical article, by Mr. F. W. Dunbar, in the *Electrical Engineer* of New York, the following result is arrived at:—The fundamental and first prominent overtone of the male voice reach the receiving instrument at Chicago with a difference in phase of 90deg. When the octave is zero the fundamental is a maximum, and *vice versâ*. The remaining component parts of the complete tone arrive with their phases varying throughout the entire 360deg. The resultant tone should be perfectly inarticulate if any such action limited in any degree the transmission of speech or music telephonically. But the displacement of phase in the case cited is similar to that which exists whether a person listens to a vocal duet from a distance of 20 or 21ft. from the performers. Pitch 160 and its octave will vary from coincidence to a difference of 90deg. in phase by the change in position. The ear is an analytic organ, and appreciates the component parts of the complete wave whatever their phase difference may be. We may fear no limit to telephony from this cause.

The Heat Produced by Dielectric Polarisation.—Herr A. Kleiner, in a recent number of *Wiedemann's Annalen*, has made some interesting and curious observations on the heating of dielectrics, by means of a thermo-couple of copper and nickel placed inside a condenser insulated with plates of various materials. Calling the heat produced in an ebonite condenser with circular tinfoil plates after a certain number of periods 1, then similar plates of other materials, treated in a similar manner, produce quantities of heat represented by the following numbers:—Paraffin wax = 0, mica = 0·28, glass = 0·74, india-rubber = 1·41, kolophonium = 0, wax = 0·6, gutta-percha = 0·76. In spite of all attempts by variation of the conditions of experiment, no heating could ever be detected for paraffin or kolophonium. Condensers made of the latter materials add to the property of high and robust insulation that of short period of charge. The author concludes, therefore, that dielectric polarisation does not necessarily involve conversion of energy, and points out the analogy between these observations and hysteresis in magnetic polarisation.

The Electric Lighting Delay in the City.—The following letter, signed L.B. and G.B., appeared in the *City Press* of Saturday last:

"SIR,—Twelve months ago we had our house wired for the electric light, and made a contract for fittings to be put in when the time came for the City of London Electric Lighting Company to supply current, which we were given to understand would be by the middle of the year, or before September last. Upon making inquiry we were informed by this Company, in writing, that the current would be available within the next two or three weeks. This promise has been repeated several times since, but now complete ignorance is affected. Upon the strength of the promises made by the Company we had the fittings put up, and unfortunately they are close to the gas fittings, so that they have been greatly damaged by our having been compelled to use the gas again all over the place. We have hardly any doubt that we can hold the Company responsible, but we write to your valuable paper for the purpose of ascertaining whether there are

Digitized by Google

other people in the same position as ourselves, who also comprehend that those who have rights also have duties, and that if the Company has the rights and the monopoly it must also carry out its duties. We enclose our card, and shall be obliged if you will give our names to anyone who wants to join us in seeing what can be done in the matter."

Newcastle.—The Members of the Newcastle Watch Committee were, says the *Newcastle Daily Leader*, thrown into a flutter of excitement at their last meeting, by the contents of a communication which had been received from the Newcastle and Gateshead Gas Company, which seems to show that the latter are determined to fight the electric light. The letter stated that owing to the partial adoption of the electric light by the Corporation the special discount of five per cent. which it has been customary to allow the Corporation will in future not be allowed, and further that the Gas Company intend to charge for the lamps up to March which had been extinguished owing to the lighting of Grey-street and other places by the electric light. The Company charge the Corporation a fixed rate per street lamp, but a number have not been in use for a considerable time owing to the new light being adopted, and it is the intention of the Company to charge for the lamps as though they had been used up to March. This will, of course, amount to a large sum, while the loss of the discount alone will come to £700 per year. It was decided to take the matter into consideration at a special meeting of the Watch Committee to-day (Friday.)

Electrical Convection.—At a recent meeting of the Société Française de Physique, says *Nature*, M. Hurmuzescu showed some experiments on electrical convection in air. He finds that if you cause dissymmetry between the two discharging knobs of a Wimshurst electrical machine, by fixing a point to one of them, then, on placing a sensitive gold-leaf electroscope at a distance of about two metres, when the machine is worked, the discharging knobs being separated, the electroscope becomes charged. The electroscope becomes more highly charged when it is fitted with a point than when it has only a varnished ball at the end of its electrode. That the charge is not due to induction, but to convection through the air, is shown by the fact that the interposition of a metallic screen does not interfere with the effect, while if the electroscope is covered over by an insulating shade no electrification is observable. In addition, it is found that the charge on the electroscope is of the same sign as that of the terminal of the machine on which the point is fixed. The most marked and rapid results are obtained when the point on the machine is negatively electrified, while no effects are observed if the point is turned towards the plates of the machine.

Thermo-electric Effect due to Molecular Stress in a Single Metal.—It is well known, says *Nature*, that electric currents may be produced by heating a single metal, if there be any variation in temper, or if the distribution of heat be very irregular, and the changes of temperature abrupt. Mr. W. H. Steele has made some experiments on these effects in the Physical Laboratory of Melbourne University. A sensitive galvanometer put in circuit with a piece of iron wire showed a current when the wire was simply warmed with the fingers. This was the only metal which gave a current when at a temperature below 100°C. Altogether twelve different metals and four alloys were examined, and the effect noticed in each of them. In order to raise the wires to a high temperature without fusing them they were passed through clay tubes (stems of tobacco-pipes), and, in the case of metals having low melting points, the tube was completely filled with the metal. The highest E.M.F. obtained from iron was 0·002 volt; 0·3 volt was observed with six different metals—lead, copper, gold, tin, zinc, and antimony; while with others, *e.g.*, silver and aluminium, the effect was exceedingly small. In the case of lead the effect showed no sign of ceasing after the metal had been heated for half a day. Gold gave the highest effect, as much as half a volt being observed. Mr. Steele remarks that these phenomena are generally quite sufficient to mask the ordinary thermo-electric effect at a red heat, and that thermo-electric tables are consequently not trustworthy for high temperatures.

Newman Lawrence Testimonial.—We have been requested to call the attention of members of the electrical profession to the case of Mr. H. Newman Lawrence, an earnest worker in the field of electro-therapeutics, who finds himself in embarrassed circumstances. Mr. Lawrence was the founder, in conjunction with the late Mr. William Lant Carpenter, of the Institute of Medical Electricity, which, under the sanction and control of many eminent men and electricians, for several years did good work in electro-therapeutics. Since that institute was closed Mr. Lawrence has continued to work on similar lines. During the whole of his professional career Mr. Lawrence has steadfastly sought to raise electro-therapeutics to its proper position as a science. It has been ascertained that Mr. Lawrence has an opportunity of making his way in the United States, and it is proposed that the funds that may be raised as a result of this appeal should be devoted to furthering this object. Any members of the Old Students' Association who may read this are reminded that Mr. Lawrence was the founder and first president of that society. This fact, it is hoped, may influence at least some to support the movement herein referred to, which has the support of a committee consisting of Viscount Templetown, Mr. W. H. Preece, Profs. Ayrton, Silvanus Thompson, Victor Horsley, R. Mullineux Walmsley, Dr. W. E. Sumpner, Messrs. Gisbert Kapp, T. E. Gatehouse, H. C. Marillier and others. Subscriptions will be received by Mr. E. C. De Segundo, 28, Victoria-street, Westminster, S.W., or Mr. Thomas Adams, 24, Hillfield-road, West Hampstead, N.W.; or they may be paid into the "Lawrence Testimonial" account at Messrs. Lloyd's Bank (Limited), 54, St. James's-street, S.W.

Smoke-Prevention Legislation in Massachusetts.—The last Legislature of Massachusetts passed a law regulating the smoke nuisance in the large cities. This law provided that in the cities of over 300,000 inhabitants, after July 1, 1893, no person should "use bituminous coal for the purpose of making steam in boilers in any building unless the furnace in which said coal is burned is so built or equipped that at least 75 per cent. of the smoke is consumed or otherwise prevented from entering the atmosphere, the degree of suppression being determined by the quantity of such smoke emitted, as shown by the density and colour of the issuing smoke and the length of time which it is visible, the maximum standard of comparison being a continuous discharge of dense, dark smoke during the time the furnace is in active operation." The penalty was fixed at not less than $10 nor more than $100 for each week during which the violation of the law should continue. Acting under this law the Mayor of Boston named the Superintendent of Streets as the official to be charged with the enforcement of the Act, and the latter, in order to secure some ground on which to deal with the smoke nuisance, instituted a thorough system of inquiry throughout the city. Inspectors were instructed to see every factory and other business place where bituminous coal was used. The investigation extended to a large number of items, including the time of erection of boilers, their number and size, as well as horse-power, the area of heating surface and of chimney and smoke flues, the daily amount of coal burned and the number of hours in use of boiler, summer and winter, and any devices for smoke consumption in use or contemplated. Naturally, such an investigation, if properly conducted, could not be finished in one week or two weeks, and it has occupied nearly two months or more; but as a result a large amount of reliable information is said to have been collected.

New Year's Calls by Telephone.—Only an American paper with a limited circulation could indulge in the following insane amusement:—That enterprising newspaper, the St. Louis *Globe Democrat*, says a New York contemporary, this year indulged in New Year's calling up to date—that is, they called up every telephone subscriber in St. Louis, and wished all who answered a "Happy and prosperous New Year." There are 3,755 telephone subscribers in St. Louis, and the *Globe Democrat* has three telephones in its business office. For this occasion this number was reinforced by seven instruments, which were placed on the fourth floor of the building. Superintendent Durant, of the Telephone Company, personally superintended the novelty in New Year's calling, which was at the same time a practical test of the efficiency of the telephone

Digitized by Google

service. That it might be the more satisfactory in the latter sense, no special provision was made for the reception and transmission of messages at the central office. The regular list of telephone subscribers was divided into 10 portions, in alphabetical order just as printed, and a portion given to each of 10 operators. The calls were made in accordance with the prescribed rules of the Company, which are printed, framed, and hung up at the side of every instrument in the city. Half a minute was allowed each station called for to respond before the number was checked off as not answering, and the next number on the list was then taken up. The calls were commenced at 8:30 a.m., and the last of the greetings had been delivered at 11:55. The best results were achieved by operator McDonough, of the telephone corps. He is an expert at the telephone. He called up 514 stations in 3 hours 27 minutes, secured 260 answers, found 14 busy, 5 out of order, and 235 not in use for the day. The whole time occupied in the transmission of the messages was 53 hours and 8 minutes; the average time of each operator was 3 hours and 19 minutes, and the average rate was 113 calls per operator per hour, a little the fastest thing in New Year's calling on record.

Hysteresis in Iron and Nickel.—The *Philosophical Magazine* for the present month contains a Paper, by H. Nagaoka, on the hysteresis attending the change in length produced by magnetisation in nickel and iron. The author at first used the interference fringes produced between a plano-convex lens and a plate of plane glass attached to the end of the rod under examination to measure change in length. He found, however, that it was impossible to keep the temperature of the apparatus constant during the time necessary to make an observation, and also that there was considerable difficulty in counting the number of fringes displaced. To overcome the temperature difficulty the author has made use of the principle of the grid-iron pendulum, and has by this means succeeded in almost entirely overcoming this difficulty. In place of the interference bands he uses an optical lever, that is, a mirror fixed to a small base, to which are attached three needle points, two of these rest in a groove on the base-plate of the instrument, while the third rests on a small glass plate fixed to the end of the iron or nickel rod. The rod was placed along the axis of a solenoid which lay in a horizontal position pointing magnetic east and west. The deflection of the mirror was measured by means of a microscope with a micrometer eyepiece, such that one division of the scale corresponded to a deflection of the mirror of $0''{\cdot}295$ of arc, or to an elongation of $0{\cdot}805 \times 10^{-7}$ c.m. Experiments were made on wires of iron and nickel of different lengths, and he finds in every case that the elongation in iron and the contraction in nickel by magnetisation is accompanied by marked hysteresis. The curve of hysteresis is symmetrical with respect to the line of zero magnetising force, so that the elongation or contraction during cyclic changes is an even function of the magnetising force. When a wire has been magnetised it cannot be brought to its original length by simply reversing the magnetic field. In a note communicated to the same number of the *Philosophical Magazine*, Prof. Knott calls attention to the similarity between the effects observed by Mr. Nagaoka and those which he has himself observed in the case of magnetic-twist cycles for iron and nickel. A steady current was passed along the wire under observation, and the longitudinal field acting on the wire was gradually altered between the limits $\pm$H, and at suitable intervals observations of the twist made. It was found that with a small range of field the hysteresis curve obtained by plotting twist against field was very similar to the well-known hysteresis curve of magnetisation. With limiting fields, however, stronger than the field which produces the maximum twist, the hysteresis curve crossed itself twice and formed three loops. In the magneto-elongation cycle the change of sign of the magnetising force does not produce a change of sign in the elongation. On the other hand, in the magnetic-twist cycle, as the magnetic force passes through zero from positive to negative, the twist tends to do the same, though with a lag. The author considers that the twist, under a given combination of circular and longitudinal magnetising forces, depends not only upon the elongations but also upon some function of these forces which changes sign with each, and to which the existence of the maximum twist is largely, if not entirely, due.

Correlation of Solar and Magnetic Phenomena.—The difficulties which arise in attributing "magnet storms" to direct solar agency have been the subject of a lengthy correspondence in *Nature*, the two latest contributors to the discussion being Dr. Veeder, of Lyons (N.Y.), and Mr. William Ellis, of Greenwich Observatory. Dr. Veeder writes:—"The opinion of Mr. Whipple, quoted at p. 2 of *Nature* for November 2nd, to the effect that the solar outburst observed by Messrs. Carrington and Hodgson on September 1, 1859, was not the cause of the coincident magnetic perturbations, corresponds to my own conclusion in regard to the matter based upon evidence of an altogether different character. There was a recurrence of strong magnetic perturbations and auroras twenty-seven days later than the great magnetic storms of August 28 and September 1, 1859, thus following the general rule which is found to apply in such cases, there being a well-marked periodicity of such outbreaks at this precise interval corresponding to the time of a synodic rotation of the sun. Such recurrence manifestly could not exist if outbreaks upon the sun were able to produce terrestrial magnetic effects indifferently in all locations. In order that there may be recurrence at the synodic period the magnetic effects must proceed from the sun at some particular angle exclusively, and fortuitous outburst elsewhere, no matter how violent, must fail to have any perceptible effect. In the estimation of the writer there is no point more important in connection with solar physics than the determination of this period and this angle with the greatest accuracy possible." Mr. William Ellis is of opinion that it is "better to advance surely, if slowly, towards truth, rather than accept too hastily evidence that is incomplete. We must remember that on the occasion of the solar disturbance seen by Trouvelot, the magnets were especially quiet, not only at the time, but also before and after. But any explanation of these phenomena must include all cases. The position of things, as stated in my first letter, referred to above, still, I consider, holds, qualified only by the circumstance that, instead of one presumed case of direct relation, three are now adduced, with a fourth case (the Trouvelot observation), which unquestionably was not accompanied by magnetic disturbance. If we further consider that, since the year 1859, when attention became distinctly drawn to this question, there has occurred magnet movement, equal to and in very many cases far exceeding that accompanying the Carrington-Hodgson observation, on some 400 different days, we see on how slight a foundation the presumption for direct relation, that is of a nature more or less instantaneous in action, exists, although the general relation between the two classes of phenomena remains undoubted. Dr. Veeder, from his own point of view, supports the contention that the 1859 solar outburst cannot be taken as causing the accompanying moderate magnetic movement; indeed, there was far greater movement some three days previously, and again early on the morning of the following day; but in regard to his affirmation that there exists a well-marked periodicity in magnetic outbursts corresponding to the period of the sun's rotation, whilst this in a limited sense may be in some degree true, I cannot say that my personal acquaintance with magnetic records during very many years enables me at present to accept such conclusion as a general one, or, indeed, what as a consequence follows, that anything really depends on the position in rotation which the sun occupies relatively to the earth. The whole subject is, however, exceedingly interesting, and various considerations arise. One bearing on the present question may be mentioned. Great terrestrial magnetic disturbances are evidently in character cosmical, produced, it would seem, or stimulated, by some external cause. For it has been shown (*Proc. Roy. Soc.*, Vol. III., p. 191) that, on occasions of unusually sudden magnetic disturbance, the commencement of disturbance, at places so widely separated on the earth's surface as Greenwich, Pawlowsk and Bombay, is simultaneous within a much smaller limit of time than had before been supposed. Such sudden simultaneous action would thus appear to indicate an impulse, solar or otherwise, from without, but whether one distinctly solar, or in what other way produced, is a question yet to be determined."

MORE MAGNETIC MYSTERIES.*

BY S. EVERSHED.

The specific gravity of a substance may be determined by hanging a mass of it on the end of an elastic wire and noting its period of oscillation about a vertical axis. The radius of gyration, elasticity, and length of the wire being calculated, and air friction allowed for all the data for finding the mass, and therefore specific gravity of the substance, are to hand. But although an interesting problem for a third year student it is not quite the best way of going to work if our end is to measure specific gravity. It would be better to weigh the substance in the usual manner. We are led to make these apparently inconsequential remarks after carefully reading Mr. Thomas Gray's Paper, in which he works back from the curve of current time in an electric circuit embracing iron to the magnetic cycle, and hence the hysteresis loss in the iron. Very interesting and instructive the curves undoubtedly are, but the method cannot be seriously advanced as accurately determining the magnetic constants of iron.

After referring to the more or less well known methods of measuring magnetic qualities of iron involving the use of a ballistic galvanometer, and remarking that with large masses of iron the growth of induction becomes too slow for the galvanometer, Mr. Gray says:—

"It occurred to me, somewhat more than a year ago, that the cause of the difficulty in the ordinary method of measuring magnetic quality in large masses of iron might be made an advantage if the method of experiment were changed; that, in fact, the desired information might be more easily obtained by recording, not the total value of the induction for each of several particular values of the magnetising force, but the curve showing the rise of current with time, immediately after the circuit is closed. Preliminary experiments showed that, for many of the cases most difficult by the ordinary method, this could be done both accurately and easily. In these preliminary experiments the coils of a large electromagnet, having laminated cores and pole-pieces, were joined in circuit with a storage battery and a non-inductive resistance. An automatic arrangement was devised, by means of which the circuit could be closed and the instant of closing recorded by a chronograph. The ends of the non-inductive resistance were at the same time connected to the quadrants of an electrometer. At any desired interval after the closing of the circuit the electrometer could be disconnected from the resistance, and the instant of disconnecting recorded by the chronograph. The deflection of the electrometer needle then showed the difference of potential between the ends of the non-inductive resistance at the instant when it was disconnected. By this means a sufficient number of points on the curve of rise of current could be observed to enable it to be drawn. The results obtained in these early experiments agree with those given in this Paper, and the method may be found useful in cases where the rise of current is too rapid to allow of the successful operation of the method since used. It is evident that a modification of this method with a ballistic galvanometer substituted for the electrometer could be easily arranged to give satisfactory results. The ordinary ballistic galvanometer and induction coil method can also be used with a break circuit arrangement, allowing the total time integral to be taken by steps. This method of experiment was not used after the preliminary results for which it was devised had been obtained. It was abandoned, partly because of its considerable complication, but mainly because a considerable number of separate experiments are required to obtain the complete curve, thus involving a corresponding number of independent magnetisations of the magnet.

"The arrangement of the apparatus used in the experiments, the results of which are here illustrated, is shown in the annexed diagram (Fig. 1). In this diagram M is the electromagnet experimented on; C, a commutator for reversing the battery, or, when the connection to it was as shown by the dotted lines, for simultaneously cutting out the battery and short-circuiting the magnet coils; B is the battery, and R a resistance of about one ohm in its circuit to prevent excessive current, when, by the operation of the commutator, it is for an instant short-circuited; G is a mirror galvanometer, nearly 'dead beat' and of short period; L, the galvanometer lamp; *Ch*, a chronograph, and S, a key for closing the circuit. The drum of the chronograph is 14in. long and 20in. in circumference, and it can be run at a rate of one turn per minute or of six turns per minute, the speed being in each case almost perfectly uniform. The galvanometer lamp stand was provided with cross-wires, the galvanometer with a light plane mirror, and the cross-wires were clearly focussed on the chronograph sheet by means of a lens placed between the lamp and the mirror. The chronograph sheets were, for convenience of experiment and subsequent reduction, formed of 'cross-section' paper, the cross-lines on which were one-tenth of an inch apart.

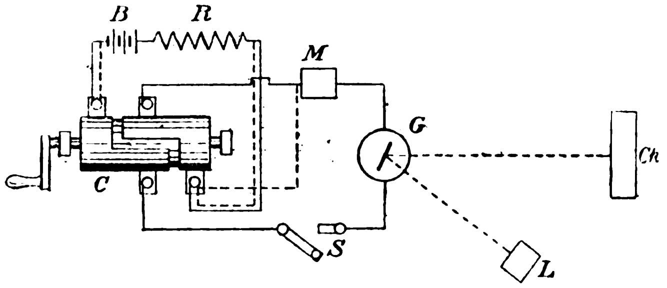

FIG. 1.

"The method of experiment is simply to hold the finger on the switch S and observe the motion of the chronograph until the image of the cross-wires comes to a particular line on the paper sheet; at this instant close the switch, and then follow the image of the cross-wires with a soft sharp pencil, dotting the line occasionally, but taking care not to influence the motion of the chronograph. When the deflection has reached a maximum, the commutator is suddenly turned as the image of the wires passes a known position and the cycle of reversal marked out on the paper. The chronograph is now stopped, and the complete curve lightly marked. The experiment is then repeated, the image of the wires being simply observed as it passes over the curve, and any disagreement noted. Any disagreement being corrected and tested, the

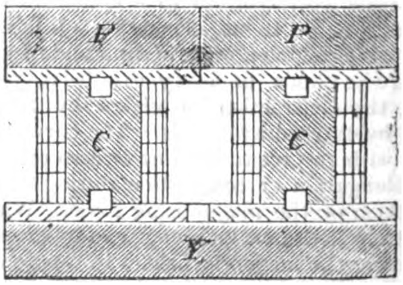

FIG. 2.

curve is ready for reduction. The time required to take a complete set of curves, check, and correct them, only requires a few minutes, after a little dexterity has been acquired in dotting out the curves. The curves obtained by this method have the advantage of being drawn to a large scale, the galvanometer sensibility being varied by means of shunts, so as to make the double deflection nearly cover the whole breadth of the chronograph sheet, while for many of the experiments made the length of the diagram extended several times round the drum. I am at present constructing an automatic recording apparatus on the principle of the Thomson recorder for the purpose of drawing diagrams for smaller masses of iron, where the interval of time is so short as to make the initial motion of the spot of light too rapid to be followed with certainty. Should this apparatus prove successful, I hope to apply it to investigate the effect of cyclic speed on the dissipation of energy, using a varying impressed E.M.F.

"The results here quoted were obtained from experiments on a large electro-magnet belonging to the Electrical Labora-

* "On the Measurement of the Magnetic Properties of Iron." By Thomas Gray. *Phil. Trans.* 1893.

tory of the Rose Polytechnic Institute, Terre Haute, Indiana. I have, however, found it easy to trace curves for an ordinary 6,000-watt transformer, although the time is in this case considerably shorter than that required for the magnet. I hope to supplement the results here given by results for various transformers, as soon as they can be reduced. The electro-magnet was constructed in the shops of the Rose Polytechnic Institute, and was designed by my colleague, Dr. C. L. Mees, and myself, for convenient use in the instruction of students in magnetic measurements. It consists of two cores, C C (Fig. 2), each surrounded by four coils of insulated wire. The cores CC rest on a yoke Y, and on the top of the cores the pole-pieces P P rest. The length of the iron circuit can be varied by moving the cores further apart and pushing forward the pole-pieces. To facilitate this operation, a screwed rod is run from end to end of the yoke, sunk just beneath the surface ; one half has a right, and the other half a left-handed screw, which work in half nuts fixed in the cores. Thus, by turning the screw, the cores can be moved apart or brought closer together. A similar arrangement serves to move the pole-pieces, and to pull them apart after they have been strongly magnetised on closed circuit. When an air space is left between the pole faces, the magnetic attraction is resisted by distance pieces, placed between the poles. The necessity for the somewhat elaborate arrangement just described arises from the great weight of the pieces, the cross section of the iron circuit being about 50 sq. in., and the length of the yoke 40in. The cores and pole pieces were constructed of soft homo-

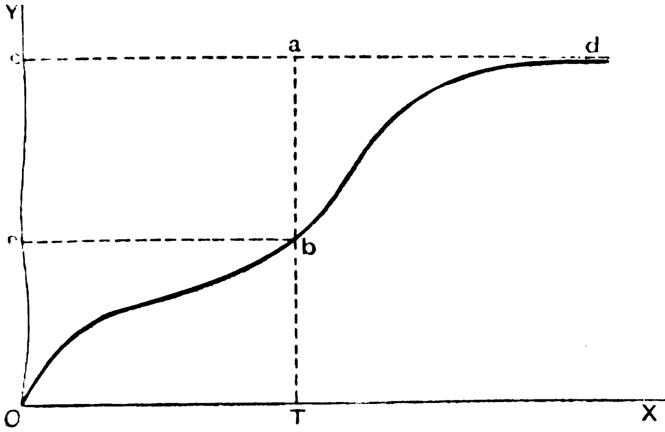

FIG. 3.

geneous iron, laminated in sheets one-twentieth of an inch thick. The insulation between the sheets and between the bolts and the holes is simply the oxidised surface of the rolled metal coated with shellac varnish.

"Let the impressed E.M.F. be E, the resistance of the circuit R and the current at any instant C. Then $E-RC=e$, the back E.M.F. on the magnetising coil due to induction. This is also equal to $L\,(dC/dt)$, and hence we have $e=E-RC=L\,(dC/dt)$ or $e\,dt=L\,dC$. Consider the curve $O\,b\,d$ in the diagram (Fig. 3), to be a curve showing the relation between current and time immediately after the magnetising circuit is closed. Let the distance along O X to any point represent the interval of time t_2-t_1 and the vertical ordinates the successive values of R C. Then the maximum vertical ordinate $Oc=E$, and the line ab corresponding to any time T is the value of e at that time. Hence the area $O\,b\,a\,c$ is the value of the integral $\int_0^T e\,dt$ or of $\int_0^{C_T} L\,dC$, the total change of induction from the time of closing the circuit to the time T ; the current being supposed zero when T is zero. By means of this curve the total induction produced by any current between zero and the maximum that the impressed E.M.F. is capable of producing can thus be studied. Again, by drawing tangents to the curve at points corresponding to different values of the currents flowing through the circuit, the value of dC/dt and, consequently, of $e/(dC/dt)=L$, the coefficient of induction at any instant, can be obtained for different values of the magneto-motive force applied, or by comparison with the curve of total induction, for different degrees of magnetisation. Similarly, if the curve of variation of current from maximum in one direction to maximum in the other direction, due to a reversal of the impressed E.M.F. be traced, the various changes of total induction, and of L through a complete cycle can be studied. The curve of total induction for the cycle forms generally, as is well known, a closed loop. The area of this loop is the difference of the values of $\int e\,C\,dt$ for the two halves of the cycle, and, consequently, is proportional to the energy dissipated in a cycle of magnetisation. This area includes the dissipation due to magnetic retentiveness, and also that due to currents set up in the iron or in conducting currents surrounding the iron. It is interesting to study these curves, as is done for a few cases below, for different conditions of the magnetic circuit.

"The curves in Figs. 1—6 show (Plate 5) the rise of current through the circuit of the electromagnet with different impressed E.M.F.s. The full line curves were obtained after the

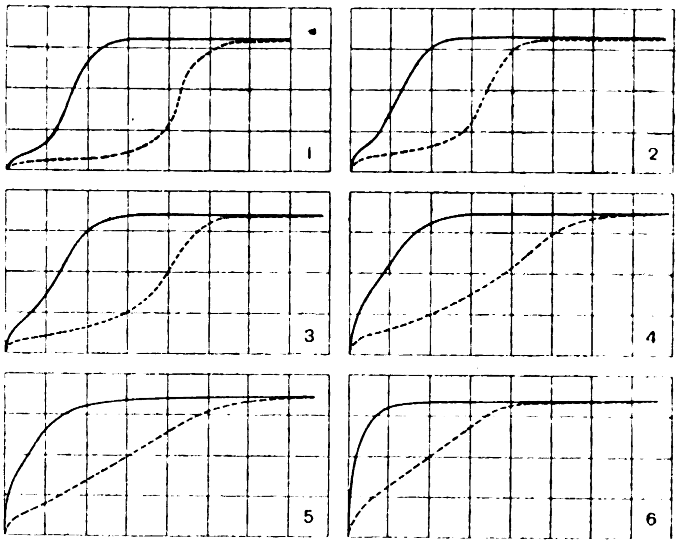

PLATE 5.—Curves showing time-rise of current for different E. M. F. on terminals. Full line, direct ; dotted line, reversal.

magnet had been several times magnetised in the same direction as that produced by the current, while the dotted line curves show the rise of current when the magnet had been previously magnetised in the opposite direction by a current of the same maximum strength. The iron circuit was closed during these experiments, and had a mean length of about 265 cms. It will be observed from these figures that the time required to complete the magnetisation is nearly inversely proportional to the E.M.F. applied to the poles of the magnet, and, also, that the shape of the curve changes considerably with change of impressed E.M.F."

It is always difficult to lay one's finger on the weak link in an apparatus like that shown in Fig. 1, and, speaking off-hand, we should have anticipated an error of uncertain amount in the mass-inertia of the galvanometer needle and mirror, and the vagueness of such a thing as a "nearly dead-beat" instrument. However, the man who actually uses the apparatus soon discovers its weakness. A born experimenter—Mr. Gray is evidently that—will often overcome the most alarming difficulties, as in the present case, that of following up the image of the galvanometer cross wires on the chronograph by hand with a pencil.

The curves in Plate 5 call for no remark, and as they are the resultant of several effects—namely, coercive force and eddy currents in the iron core, stray induction threading the coils, and so on—we shall not follow Mr. Gray in his discussion of their shape and the variations in the times at which L for the whole circuit arrives at its maximum. This sort of induction coefficient, due to everything in the circuit which can affect the rate of change

Digitized by Google

of current, may be called the gross coefficient of self-induction, and curves of its variation with time for a particular circuit are only of interest to those who have to use that circuit. In Fig. 12 (Plate 8) Mr. Gray shows the whole history of the circuit during the time occupied in reversing the current. The current-time curve is shown as a full line, while the dotted line is the value of gross L plotted with relation to current. The dot-dash loop is the cyclic power curve; its area gives the work done in hysteresis and eddy currents. It is obtained, of course, by plotting values of E – C R, that is to say, back E.M.F. for successive values of C and its area is equal to $\int e\,C\,dt$. The maximum value of the *induction density* on *the assumption that the whole amount of induction is in the iron core* is loosely described in the figure as "total induction." This maximum is obtained by measuring the area O *b d* c O in Fig. 3, and dividing it by the sectional area of the core.

Fig. 12 being obtained when the magnetic circuit was closed, the assumption we have italicised is, of course, very nearly true; but in Figs. 14 and 16 (Plates 9 and 10), which are similar sets of curves taken when the poles P P, Fig. 2, were separated by 0·5cm. and 2cm., the leakage induction is clearly very considerable, and the value given for maximum induction density, although as before,

$$\frac{\text{Maximum total induction threading the coils}}{\text{Sectional area of core}},$$

is now, as it stands, a meaningless and therefore misleading quantity.

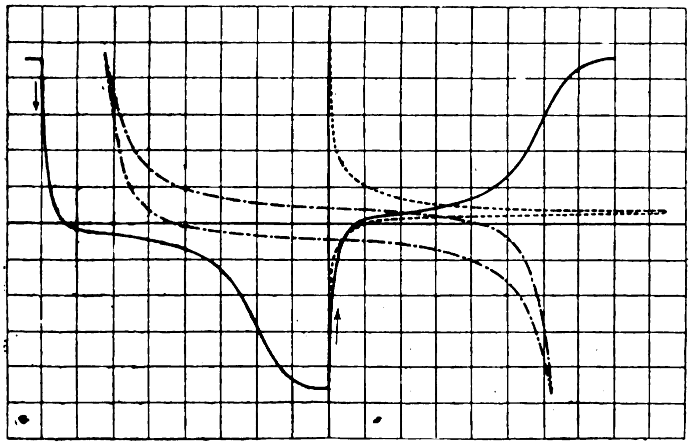

PLATE 8. FIG. 12.

Full lines = curves for reversal of current. 23 (28 ?) divisions = 10 amps.
Dotted lines = coefficient of induction L. One division of abscissæ 10^{11} cms. One division of ordinates = 5 volts.
Chain-dotted lines = Total induction (total = 15,200 C.G.S. units per square cm). Energy dissipated = $1{,}534 \times 10^6$ ergs.

Accordingly we find a large part of the remainder of the Paper devoted to the discussion of the supposed magic effect of an air gap in diminishing the hysteresis and eddy-current losses in the core. Commenting on the marked difference between Fig. 12 and Fig. 14, Mr. Gray remarks "we find, as one of the most noticeable features, the evidence they (the curves) afford of the great effect a small air space has on the magnetic retentiveness of the magnet," and goes on to say :—

"Of course, a direct comparison of the amount of energy dissipated in the cycle cannot be made from these curves alone, but a separate set of experiments, illustrated in Figs. 22-27, brings out the result that considerably less energy is dissipated on the open circuit for the same amount of total induction than is the case with the closed circuit. From the curve (Fig. 26) it appears that the energy dissipated per cycle on closed magnetic circuit for total density of induction of 13,200 C.G.S. units is 92×10^7 ergs, while the actual experiment on open circuit only gives 74×10^7 ergs, the air-space being only half a centimetre. Again, from the same curve, it appears that, for closed magnetic circuit and a total density of induction of 8,610 C.G.S. units, the energy dissipated per cycle is 4×10^8 ergs, while for the actual experiment, with two centimetres of air-space in the circuit, it is only 3×10^8 ergs per cycle. This is equivalent to a saving of about two and a-half foot-pounds of energy per cycle. That the dissipation of energy due to magnetic retentiveness becomes comparatively small when the distance between the poles is as much as half a centimetre, was proved by static experiments made for the purpose. These experiments showed that, for a total induction of 14,000 C.G.S. units per square centimetre across the air-space, the dissipation, as measured by the variation of the field in the air space, was only 590×10^6 ergs. The intensity of magnetisation here quoted was obtained with about 130 *volts* on the terminals of the magnet, and approaches near to saturation of the cores. When the circuit is open the dissipation of energy is largely due to Foucault currents in the iron, and, as will be seen from the values calculated and marked on the curves, it approaches towards being proportional to the square of the induction through the iron. This is a result which we should expect so long as the law of the variation of the induction is not very different in the cases compared. The practical bearing of the result here arrived at on the question of open *versus* closed circuit transformers is evident."

"Tell a lie and stick to it!" Dame Nature having cleverly deceived Mr. Gray in the current-time observations tells him a bigger lie when he appeals to her for confirmatory evidence by way of static experiments. Why Mr. Gray chose the air-gap as the place for the measurement of variations of induction is a mystery. By doing so he missed all the induction traversing a part only of the iron cores, and returning through the air without going near the air-gap, and consequently failed to find

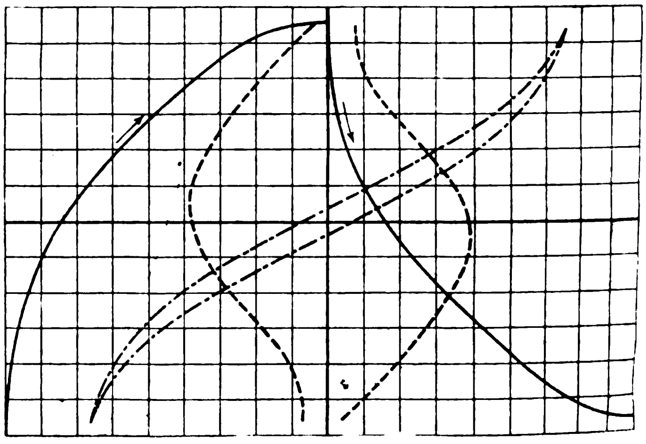

PLATE 9. FIG. 14

Magnet poles separated 5 millimetres. R = 11·5 ohms. Total induction per square cm., 13,200 C.G.S. units.
Full line, curve of reversal of current, 28 divisions = 10 amps.
Dotted line, curve of coefficient of induction L. One division of abscissæ = $34{\cdot}4 \times 10^9$ cms. 5·6 divisions of ordinates = 23 volts.
Chain-dotted line = total induction, ordinates ½ area of L curve. Energy dissipated, 742×10^7 ergs.

a considerable portion of the wasted energy. The truth is, the smallest air-gap causes a very large leakage of induction, as the following experiment carried out by Mr. Vignoles and the present writer in November, 1889, clearly shows. A ring of iron 10 cms. in diameter, and 1 cm. in sectional area, was wound with primary and secondary (ballistic) circuits with a small clear space left where the ring could be sawn through. Having first obtained the **B H** curve from the uncut ring, it was sawn across, leaving an air-gap 0·16cms. in length, and now, out of 15,000 thoms found in the iron at a point on the ring exactly opposite the saw cut, only 9,000 reached the air-gap. The remaining 6,000 cut across through the air from one side of the ring to the other. Had we determined the hysteresis loss from the B H curve of the air-gap the result would obviously have been far too low. Mr. Gray found the loss fall from 92 joules to 74 joules when he opened the magnetic circuit by 0·5cm. This diminution is fully accounted for if the average induction-density in the iron fell from 13,200 to 11,500, the remaining induction being easily accounted for by leakage, as we see from the experiment just described.

The remainder of the paper is devoted to observations of the effects on closing the secondary circuit of the magnet used as

Digitized by Google

a transformer, and a discussion of the law of variation of hysteresis loss with induction-density. The author's conclusion on this point is best given in his own words :—

"The effect of varying the impressed E.M.F. on the dissipation of energy is illustrated in Figs. 22 to 25, the abscissæ of which are proportional to the impressed E.M.F., and the ordinates to the induction as calculated from the reversal of current curves which were similar to that shown in Fig. 12. Although the number of experiments here shown are not sufficient to allow any law to be accurately deduced from them, the

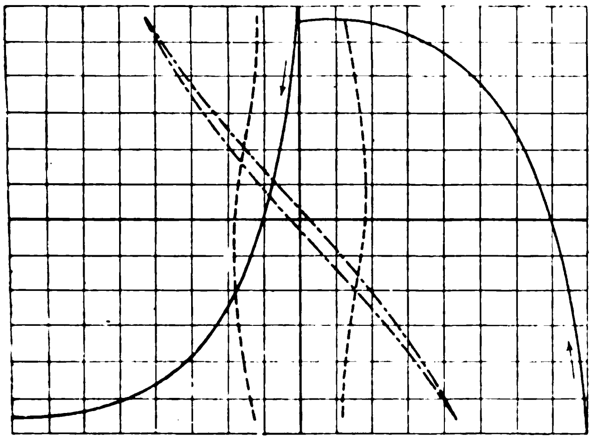

Plate 10. Fig. 16.

Magnet poles separated, 2 cm. Ordinates for L curve = 1 division to $34\cdot4 \times 10^{6}$ cms. Ordinates for B curve = 1 division to ½ area of L curve. Total induction per square cm. = 8,610 C.G.S. units. Energy dissipated, 298×10^{6} ergs.
Full line = curve of reversal of current. 28 divisions = 10 amps.
Dotted line = coefficient of induction L. 5·6 divisions = 23 volts.
Chain dotted line = total induction = per square cm., 8,610 C.G.S. units.
This Figure has been accidentally reversed in engraving, and should be read from right to left.

results are shown by the black dots in the curves Figs. 26 and 27. Fig. 26 is drawn from an equation of the form $e = \text{A E} + \text{B I}$, where e is the energy dissipated, E the impressed E.M.F., I the total induction, A and B constants. For this

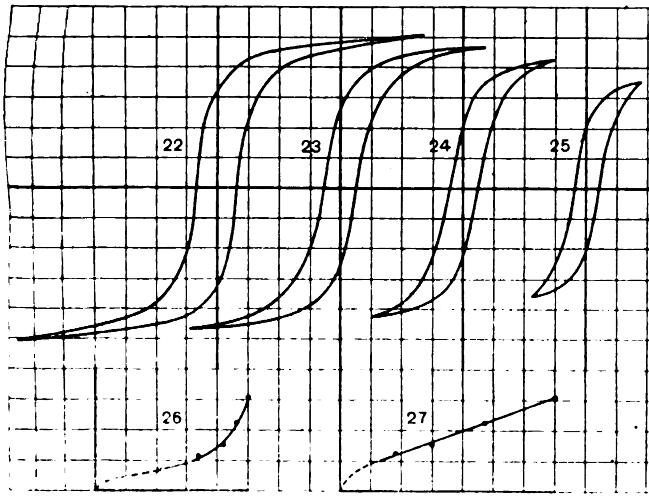

Plate 16.

For Figs. 22 to 25, Ordinates × 3,000 gives induction in C.G.S. units per square cm. Abscissæ ÷ $\frac{1}{10}$ gives effective E.M.F. in volts. Resistance of circuit = 11·5 ohms. Number of turns on magnetising coil = 3,840. Length of iron circuit, 265 cms.

Fig 22.—Dissipation = $1{,}534 \times 10^{6}$ ergs.
„ 23.— „ = $1{,}126$ „
„ 24.— „ = 771 „
„ 25.— „ = 598 „

Fig. 25.—Induction $\frac{1}{10}$ division = 300 C.G.S. units per square cm. Total dissipation = 75×10^{5} ergs.
Fig. 27.—Impressed E.M.F., 3 div = 10 volts. Total dissipation = $1{,}500 \times 10^{6}$ ergs.

particular curve A = ½ and B = 25,300. The curve shown in Fig. 27 has impressed E.M.F. for abscissæ and dissipation for ordinates, and is drawn to show that for the range of experiment taken the dissipation was practically proportional to the impressed E.M.F. Independent experiments indicate that the amount of energy dissipated in the secondary circuit when the magnet is used as a transformer, in the way above described, is nearly proportional to the impressed E.M.F., and hence this was assumed to be the case for the Foucault currents also. The other constants were then obtained by solving for them by means of simultaneous equations of the form $e = \text{A E} + \text{B I}^{x}$, the necessary data to form the equations being taken from the experimental results. It was found in this way that x was practically unity, not differing by more than 1 per cent. for the cases taken, and hence it is taken unity in the curve. The results of static experiments would indicate that the term B I^{x}, which represents the energy dissipated due to the retentiveness of the iron, should vary more rapidly than the induction, that is, that x should be greater than unity, about 1·6 for the experiments of Ewing and others. This result does not seem to be reached by the kinetic method here adopted, and an examination of recent work on the subject seems to confirm the results here arrived at."

In reading this passage it should be remembered that Mr. Gray's paper was written early in 1892; since then many doubtful issues have been finally set at rest, and among them we may consider it to have been conclusively shown by Mr. Steinmetz that hysteresis loss in iron varies as the 1·6th power of the induction-density. It is true that this law is based solely on experimental results, but we are confident that a rational explanation is almost within reach.

In concluding our notice of an interesting and novel experimental research it is only fair to say that Mr. Gray had discovered the unsound nature of his conclusions before the publication of the paper, and in a note added in June, 1893, he says that "the conclusions arrived at in the paper," with respect to variation of hysteresis loss with induction-density "are undoubtedly wrong." We have been too often led astray by some magnetic Will o' the Wisp, not to extend our sympathy to Mr. Gray in his struggles with the same tangled mystery, but we cannot avoid contrasting the feverish haste to publish of our own day, with the leisurely cautious reticence of Newton, and one is tempted to believe after all that much of our progress has been "crab-like—sideways."

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, January 26th.

Association of Technical Institutions.

2 30 p.m. Meeting at the Society of Arts for constitution of Association.

Physical Society.

5 p.m. The following Papers are down to be read: (1) "A New Mode of Making Magic Mirrors," by J. W. Kearten. (2) "Some Observations in Diffraction," by W. B. Croft, M.A. (3) "A New Photometric Method and Photometer," by J. W. Spurge.

Electro-Harmonic Society.

8 p.m. Smoking Concert at the St. James's Hall Restaurant (Banquet Room), Regent-street, W.

MONDAY, January 29th.

London Chamber of Commerce.

3 p.m. Meeting of the Electrical Trade Section at Botolph House, Eastcheap. Agenda: (1) Antwerp Exhibition, (2) Report of the Action of the Traction Committee, (3) Appointment of a Parliamentary Committee, (4) Others matters.

Society of Arts.

8 p.m. Cantor Lecture. "The Detection and Measurement of Inflammable Gas and Vapour in the Air," by Frank Clowes, D.Sc.

TUESDAY, January 30th.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. The following Paper to be further discussed: "The Tunnels of the Dore and Chinley Railway," by the late Percy Rickard, M.Inst.C.E. Paper to be read (time permitting): "The Transport of Petroleum in Bulk," by Mr. Boverton Redwood, F.R.S.E.

THURSDAY, February 1st.

Institution of Mechanical Engineers.

7 30 p.m. Annual General Meeting at 25, Great George-st.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

SPECIAL NOTICES.

With this week's Number of "THE ELECTRICIAN" we publish (Gratis to Subscribers) a fine STEEL-PLATE PORTRAIT of Mr. ALEXANDER SIEMENS, President of the Institution of Electrical Engineers for 1894.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; and Mr. Alexander Siemens, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

THE NIAGARA SCHEME.

"W-I-N-D-E-R—'Winder.' Now go and clean it," said Mr. SQUEERS; and having told us how he meant to build his dynamos and construct his subway, it might have been imagined that Prof. G. FORBES would merely go across the Atlantic and see the job through. But it seems that we have not come to the end of the preliminaries yet, for each week brings some interesting news about the Niagara scheme. Whether the whole will be completed or whether a part only will be set at work, and whether it pays or not concerns us but little. Most of our readers regard this undertaking only as a magnificent bit of electrical engineering. An alternator driven by a vertical shaft turbine is commonplace enough, but the modifications which are rendered necessary simply on account of the large scale give a great interest to the design. If present plans are carried out the Niagara generating plant will be the largest in the world, but it must be remembered that it cannot be compared either in magnitude or in usefulness with the one-man scheme of the original Deptford station. At Niagara there are to be several 5,000 H.P. alternators, and the first of these is, we suppose, in an early stage, if, indeed, it be actually in hand. At Deptford there were to be four 10,000 H.P. alternators, with 36in. shafts and 45ft. armatures, and considerable progress was made with the first machine before difficulties entirely unconnected with this part of the work caused the construction to be suspended. The ForthBridge cannot be expected to pay appreciable interest

Digitized by Google

on the capital expended upon it, and the financial result is, indeed, a somewhat complicated matter; but even if it had ruined the railway companies who support it, its interest as an engineering achievement would not have been touched. It has been suggested that the value of a horse-power, day and night, at Buffalo is about £5, and that this will yield an income of £2,455,000 per annum. We have shown, more than a year ago, that this leaves but small margin, if any, for competition with steam, and both Mr. Swinburne and Mr. Crompton have recently alluded to the financial side of the question as though the payment of interest upon the capital expended on the plant—this interest being earned by income from power rental—were the only measure of success. In many undertakings this is the case. The familiar tide-mill problem, 200-miles-an-hour railways, and Mr. Thwaite's scheme for transmission of power from the coalfields must be considered from this simple standpoint. But it is not unlikely that the Cataract Construction Company is a land company, and almost precisely as tramways are put down in America for the purpose of increasing the value of land, rather than for the purpose of earning revenue, the economical or effective working of the Niagara plant may after all turn out to be a comparatively unimportant item of the whole affair.

Prof. Forbes has recently made four declarations about Niagara, solemnly prefaced by the words, "The following statements are true." The one of these which concerns us at present runs as follows:—"The Niagara enterprise is probably the first American enterprise that ever came to Europe saying, we have already subscribed our capital in America, and we are ready to exchange such portion of our cash as may be necessary to secure the brains to properly conduct our enterprise. I confess I am ashamed of my countrymen, and cannot imagine what is the animus which has led to so wilful a misconstruction of such liberality, foresight, and straightforward dealing." Now it happens that among the wild investments of one of our unfortunate English Trust companies, whose affairs have of late been receiving so much attention, we find shares in the Cataract Construction Company which have been recently valued at $1,205,207, being First Mortgage Scrip, together with three $50 Ordinary shares. We have no means of learning whether the valuation was made at par or at the purchase price; but we must conclude that either Prof. Forbes was mistaken on this point, or that his liberal and straightforward-dealing friends have already begun to unload for the benefit of his countrymen, of whom he is ashamed. Prof. Forbes, however, has his hands full of technical matters, and this little matter is probably outside his department.

In connection with the fact that the Westinghouse Company, of Pittsburgh, were not included among those to whom Prof. Forbes expressed his indebtedness in connection with the design of the plant, the letter, of which we gave an abstract on p. 292 of our last issue, is the more remarkable. There are generally two sides to a question, and even if Prof. Forbes makes no reply, the result will be watched with interest. This firm did not take part in the competition for designs, and it appears that it was not until Prof. Forbes' designs were laid before them that they declined to carry them out, and were requested to submit their own plans and specifications, which were accepted by the Cataract Construction Company. Hard things have been said about the competition for designs, and we have made a few inquiries on the subject. Out of six of the competing firms, three tell us that they went into the competition with their eyes open, and with the prize only in view, one firm says that they are not at all satisfied with their relations with the Cataract Construction Company, that their scheme "was sent in with the intention of supplying the plant," and that they sent one of their engineers to America on the business. Another firm sent in designs for the second competition when "no prizes were offered, but it was quite understood that the construction of the machines would be entrusted to one of the competing firms, or else that the machines would be made in America from their working drawings, for which they would, of course, be paid. . . . For the machines we sent in designs, which were very favourably spoken of by the experts, indeed the whole tone of their letters was such as to make anyone believe that the decision was practically for us. In the course of a long correspondence they obtained from us a large amount of useful information, for which we received—their thanks." The sixth firm declines to reopen the, perhaps, rather sore subject. From these replies we gather that Mr. Ferranti's attack, at the discussion on Prof. Forbes' Paper, was based on the complaints of only one or two firms, or on statements made by those whose disappointment had considerably cooled down by the time our inquiries were made. In any case, there is no reason to suppose that Prof. Forbes was concerned in this part of the affair. Another of the statements which Prof. Forbes recently made was that "it has been generally understood that no private undertaking has paid so much for engineering advice in advance of contracting as the Niagara project." This seems very natural, and it is perhaps equally natural that complaints should arise. According to a cablegram received from our New York correspondent, Prof. Henry Rowland, of Johns Hopkins University, having sent in a bill for $10,000 for services rendered to the Cataract Construction Company, and receiving only $3,500, sued the Company for $30,000. The result has been a "sensational trial," and a verdict for Prof. Rowland for $9,000; evidence being given on one side or the other by Mr. Coleman Sellers, Prof. George Forbes, Dr. John Hopkinson, Dr. Louis Duncan, Mr. Frank Sprague, and Mr. William Stanley, Junr. This is the latest bit of news about the Niagara scheme. We wish it every success, and hope that it will do somebody credit.

ALEXANDER SIEMENS.

Mr. Alexander Siemens, whose steel-plate portrait we publish this week, was born at Hanover in 1847, and was educated at the Lyceum and Polytechnic College there. In 1867 he came to England, and worked for a short time at the telegraph factory of Messrs. Siemens Brothers at Woolwich. In the following year he went to Berlin to study at the University, and remained there until 1870, with the exception of filling a temporary engagement, during which he assisted in constructing the Indo-European telegraph line from the Persian frontier to Teheran, and in laying the Black Sea cables at Kertch and from Sukhum Kale to Sotcha. He was next called upon to serve his country in the Franco-German war, and was present at the siege of Metz, and afterwards, under Prince Frederick Charles, joined in the operations against Orleans. He was wounded at the battle of Beaune la Rolande, and for his distinguished services in the field received the Iron Cross.

At the conclusion of the war Mr. Siemens was able to continue his scientific studies, and coming to England, became a pupil of the late Sir William Siemens. In 1873-4 he was conducting experiments for Sir William, at Birmingham, with a rotary furnace to produce wrought iron and steel direct from the ore. In 1875 Mr. Siemens joined the cable ship "Faraday," and took part in several cable-laying and repairing expeditions. Whilst the ship was stationed at Halifax, N.S., he built some blast furnaces at Londonderry, N.S., for the

Digitized by Google

Steel Company of Canada, and superintended the erection of a rotary furnace at Pittsburg, Pa. Returning to England in 1877, he was employed in erecting regenerative gas furnaces for various purposes in different parts of England, among them being the first continuous working tank glass furnace erected in this country. In 1879 he became actively engaged in electrical work for Messrs. Siemens Brothers, and had to do with some of the first electric light installations, such as those at the Albert Hall, the British Museum, the Albert Docks, and the Blackpool Promenade. He also laid down an electric light plant at Godalming, the first town in England to so light all its thorougfares, and supply current to private consumers.

Mr. Alexander Siemens became a Director of Siemens Brothers and Co. some time ago, and is now the only Director residing permanently in England. In 1892 he contributed a Paper to Section G of the British Association at Edinburgh on "Electric Locomotives on the City and South London Railway." He has been for many years a member of the Institution of Electrical Engineers, to which body he has contributed several Papers of great interest to the profession, the most recent being that read on February 11, 1892, upon "Some Experimental Investigations of Alternate Currents." He was elected a Vice-President of the Institution four years ago, and is President for the year 1894.

OBITUARY.

ROBERT C. HALPIN.

The announcement of the death of Capt. Robert C. Halpin, R.N.R., D.L., which took place shortly after ten o'clock on Saturday morning last at his residence, Tinakilly (Wicklow), will be received with great regret in naval circles, in London and Liverpool, as well as in Ireland. The deceased gentleman, after an illness of over three months, died of blood poisoning.

Capt. Halpin, a native of Wicklow, was born in 1836, and at the age of eleven years entered the Mercantile Marines, attaining the command of the "Circassian" barque at the early age of twenty-two. In 1864 he was appointed chief officer of the "Great Eastern," chartered by the Telegraph Construction and Maintenance Company, of which Mr. (now Sir) John Pender was Chairman, for submarine telegraph cable laying, and owing to his energy and nautical capabilities was within four years given the command in succession to the late Sir James Anderson, on the occasion of the laying of the longest submarine cable in the world, that from Brest to St. Pierre. In 1869 he was entrusted with the sole command of the British Indian Telegraph Expedition, and laid the cables from Bombay to Aden and Suez. The steamships that were used on the occasion were the "Great Eastern" "Hibernia," "Chiltern," "William Cory," and "Hawk." In 1873-74 he commanded the Brazilian Submarine Telegraph Expedition, when the cable from Madeira to St. Vincent and Pernambuco was laid in the deepest water where such lines have been established. In the same years Capt. Halpin laid two other Atlantic cables with the "Great Eastern." He was then appointed Marine Superintendent of the Telegraph Construction and Maintenance Company. Since 1869 he had successfully laid over 20,000 miles of submarine telegraph lines. At various periods during his services at sea he was presented with valuable testimonials. The French Emperor offered him the Order of the Legion of Honour, and in 1874 the Emperor of Brazil presented him with the Order of the Rose. In the same year the captains and officers of the fleet of the Telegraph Construction and Maintenance Company entertained him at a banquet, and made him a presentation. The Governor of Bombay, the Governor-General of the Netherlands (India), the Governor of Newfoundland, the Chambers of Commerce of Liverpool, New York, Bombay, Pernambuco, &c., have also publicly recognised his great qualities. In 1876 he was appointed a nautical assessor in the High Court of Judicature and a member of the Local Marine Board of the Port of London. He also became a Junior Brother of the Trinity Corporation, was subsequently made a Commander of the Royal Naval Reserve, and a few years ago was appointed a Deputy Lieutenant of County Wicklow. In 1892 he was unanimously chosen as Chairman of the Wicklow Harbour Board, and was re-elected last year. His loss will be greatly felt amongst the poor in Wicklow and by various charitable institutions, especially the Royal Alfred Institution for the benefit of aged seamen, in which he took a warm and active interest.

The funeral took place on Tuesday last and was very largely attended. The detachments of Wicklow Militia, Constabulary, Coastguard, and the multitude of carriages which followed, made a procession three-quarters of a mile long—and hundreds of people followed on foot. The Coastguard men, by their special request, acted as bearers of the coffin. One who was present says: "No man could have been more popular with all classes, and the whole district seemed to be in mourning for him."

REVIEWS.

An Elementary Treatise on Fourier's Series and Spherical Cylindrical, and Ellipsoidal Harmonics, with Applications to Problems on Mathematical Physics. By Prof. Byerly, Harvard University. (Boston: Ginn and Co.)

There is a well-known partial differential equation, which is the same in problems on heat conduction, motion of fluids, the establishment of electrostatic or electromagnetic potential, certain motions of viscous fluid, certain kinds of strain and stress, currents in a conductor, vibrations of elastic solids, vibrations of flexible strings, or elastic membranes, and innumerable other phenomena. The equation has always to be solved subject to certain boundary or limiting conditions, sometimes as to space and time, sometimes as to space alone, and we know that if we obtain any solution of a particular problem, then that is the true and only solution. Furthermore, if a solution, say, of a heat conduction problem, is obtained by any person, that answer is at once applicable to analogous problems in all the other departments of physics. Thus, if Lord Kelvin draws for us the lines of flow in a simple vortex, he has drawn for us the lines of magnetic force about a circular current; if Lord Rayleigh calculates for us the resistance of the mouth of an organ pipe, he has also determined the end effect of a bar of iron which is magnetised; when Mr. Oliver Heaviside shows his matchless skill and familiarity with Bessel functions in solving electromagnetic problems, he is solving problems in heat conductivity or the strains in prismatic shafts. How difficult it is to express exactly the distribution of strain in a twisted square shaft, for example, and yet how easy it is to understand thoroughly when one knows the perfect fluid analogy. How easy, again, it is to imagine the electric current density everywhere in a conductor when transmitting alternating currents when we know Mr. Heaviside's viscous fluid analogy, or even the heat conduction analogy.

Much has been written about the correlation of the physical sciences; but when we observe how a young man who has worked almost altogether at heat problems, suddenly shows himself acquainted with the most difficult investigations in other departments of physics, we may say that the true correlation of the physical sciences lies in the equation of continuity

$$\nabla^2 u = a^2 \frac{du}{dt}.$$

There are many men who are pretty much in my position with regard to these investigations, and possibly many physicists who know even less about them than I do.

I had the honour of attending a course of lectures on Fourier's method in heat problems delivered by Lord Kelvin to an advanced class in Glasgow twenty years ago. My carefully-corrected notes, illustrated by the solution of many interesting problems with accurately drawn curves, mysteriously disappeared just after the end of the course, and many a time since have I felt that the loss of these notes was a loss to all the average mathematical physicists of the world, for I should certainly have published them long ago. I had worried over Maxwell before I went, and I remember that in the beginning Thomson seemed to know less of Fourier than I did myself, that he felt

Digitized by Google

his way in a stumbling fashion for about two lectures, and then for the remainder of the course he was not only perfectly master of the subject, but by his enthusiasm, his knowledge of our ignorance, his pains to put things before us in such ways as he thought we could best understand, his numerous easy examples, his evasion of mathematical difficulties by giving physical proofs, and above all by his making us work out numerical examples and show our results in curves, he established himself, in my mind, as a teacher in the position which he must ever retain. I do not know how a man of leisure who has fair mathematical ability can refrain from making that sort of pilgrimage which I made to Glasgow. I shall thank God all my life for that most glorious session, during which Thomson was never once obscure, during which not one day passed without the publication to his students of valuable and otherwise unpublished information. I have known him to be very obscure in delivering a "popular" lecture or other address; but let him lecture to advanced students, with plenty of time to meander into all parts of his subject, and his lectures are one long delight, and such a great delight that I sometimes wonder how I resist the temptation to give up all my affairs in London for one more session at Glasgow just to listen to elementary lectures on subjects that I have been in the habit of teaching.

How few are the working mathematicians who know the use of Fourier's integral or spherical harmonics or Bessel functions. How many are the men who have possession of the English translation of Fourier's treatise, and who yet understand nothing of Fourier's method. How many are the men, like myself, who feel disgusted at their ignorance of a method of analysis which seems so all-important in modern mathematical physics, and which looks so hopelessly above their mathematical powers when studied here and there from occasional scientific Papers. Parenthetically I may remark that the writers of mathematical Papers are the most selfish and unsympathetic people in the world. I remember once being honoured during three months to converse almost every day with one of the great mathematical physicists. During that three months he was engaged almost continuously on an interesting problem, and I understood fairly well what he was doing. Now the whole of his investigation is published in two pages of the Mathematical Society's *Journal*, and of that publication I do not understand one word. The passion for having perfection of compactness and generalisation seems to be so intense in some of our leaders that one can only compare it with the old-fashioned habit of philosophers to publish their discoveries in such riddles as really hid their results from other philosophers, and yet enabled them later on to obtain all the credit they desired.

Everybody of my way of thinking will be delighted to know that Prof. Byerly, of Harvard, has just published "An Elementary Treatise on Fourier's Series and Spherical, Cylindrical, and Ellipsoidal Harmonics, with Applications to Problems on Mathematical Physics," which seems to be exactly what we have long wanted. I am speaking quite carefully and soberly when I say that to sit down for the first time to look through that book is like taking the first long drink at a fountain when one has just passed through a desert. And it has come unexpectedly, too; one heard nothing about its being in preparation. There are many of our leaders who might have done it, but they probably thought it below their dignity to write an elementary treatise—at all events, they did not do it, whereas Prof. Byerly, in doing it, has done a very great service to all average mathematical physicists. Here they are, those beautiful solutions of Fourier, so clearly given that anyone can understand them if he has done what so many thousands do in the differential calculus. Prof. Byerly first attacks a few problems, and shows that in all of them it is necessary to expand functions in series of terms of certain normal forms, and the first chapter is the most interesting in the book, and the first problem of the first chapter gives one the most pleasure. The first normal forms considered are sines and cosines of angles; the next are spherical harmonics, and the next are Bessel functions. It becomes evident to the reader that it is this development of a function which has become important in the solution of problems. Chapter II. shows how to develop a function in Fourier's series (or series of sines and cosines), and Chapter III. discusses the convergence of such series, showing in beautiful illustrative curves how by taking one, two, three terms, &c., successively, we approach nearer and nearer to the real function. These two chapters are very interesting, and yet I think that Prof. Byerly with all his knowledge of what a beginner ought to be taught has erred a little here and elsewhere in giving too much. I may be mistaken, but I think that I would have asked the student to draw curves himself, and refer elsewhere to exact proofs of convergence of series, and these 38 pages would have been reduced to three. On second thoughts, however, I must say that I should regret the absence of the beautiful successive approximations of pages 63 and 64. How skilfully the author has used these curves in drawing the interesting conclusions of page 65!

Chapter IV. introduces us to Fourier's integral, and to all the most interesting problems which require the Fourier developments for their solution. As the last three chapters dealt with problems needing the Fourier developments, so Chapters V. and VI. deal with developments in sperical harmonics and Laplacians, and Chapter VII. deals with problems requiring developments in Bessel functions. In Chapter VIII. we have ellipsoidal harmonics, with some information about Toroidal harmonics. In Chapter IX. we have an excellent summary of the history of the subject, by Dr. Maxime Bôcher, a colleague of the author, with a list of works of reference; and in an appendix there are certain tables of Zonal harmonics, hyperbolic functions, roots of the Bessel equation, and tables of the Bessel functions of the zeroth (used by Fourier before Bessel's time), and first orders, which might with advantage have been more elaborate.

This book suits me very well, and will be enjoyed by my advanced students, but, as I have already remarked, a much smaller book, giving the more elementary parts of the subject, with exact instructions for the working of a few good illustrative exercises, is still wanted if the results of investigations are to be brought within the power of use of the practical engineer (I mean that kind of working engineer who has not an ignorant contempt for theory, for there are such men, just as there are great mathematical physicists who have not an ignorant contempt for the workshop method of investigation). It is only given to a few to be able to solve an altogether new problem, but I would have everybody able to apply to his own special cases the results of an investigation already published. To do even more than this it is almost enough if one is able to develop any given fuction of x in one or other of the series already referred to. To develop in a Fourier's series is quite easy, and the numerical work is not very long. I gave an example in *The Electrician* of February 5, 1892. There, an arbitrary function of t, from the values $t=o$ to $t=T$, was developed in sines and cosines, and by the same method any arbitrary function of x, from $x=o$ to $x=c$, may be developed. When c is taken infinitely great the Fourier's series degenerates into a Fourier integral. If a function is represented by a curve in the usual manner, Prof. Henrici's beautiful analysing machine will give the Fourier series without mathematical work of any kind. I am in hopes that his success with this machine may induce him to design another, in which for any curve we may develop a series of Bessel functions. To do it numerically the process is not unlike the Fourier development; but, unfortunately, my students have hitherto found that the tables of Bessels available, even when extended by their own interpolations, are not nearly so good or handy as Bottomley's tables of sines and cosines are for these better-known functions. Tables such as are given by Dr. Lommel are excellent if one does not mind the labour of interpolation; but for real practical work the tables ought to be like Mr. Bottomley's. I believe that Prof. Lodge, of Cooper's-hill, has long been preparing tables of Bessel functions, and I am in hopes that he will prepare tables of Bessels of the second kind; but it is evident to everybody who has used Bessels in alternating-current problems, that something further must be done, such as taking the sum of the odd terms by themselves, and the even terms by them-

Digitized by Google

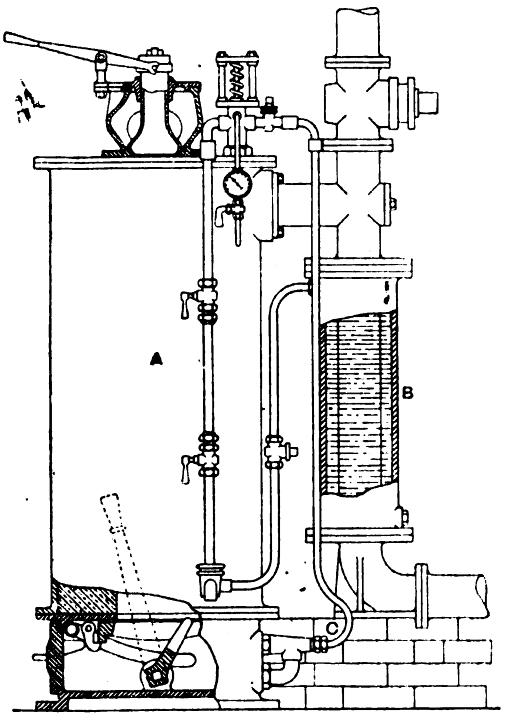
selves, of the series $J_0(ip\sqrt{i})$, where i is $\sqrt{-1}$. The real part has been called *ber p* by Lord Kelvin, and the multiplier of i in the imaginary part *bei p*. We want, as I say, plenty of tables or analysing machines, and a general simple teaching of methods of solution of problems to practical engineers, and there may then be a chance of great progress. Most of the worshippers at the numerous shrines to the goddess of stupidity (to whom I also fearfully offer up sacrifices) will sneer at the idea that practical engineers should be taught to practise these methods of analysis. And Dugald Dalgetty, who could actually extract a square root, or Cassio, who "was a great arithmetician," or much more one of the Latin or Greek sages, who could multiply by "the trireme method," would have sneered at the idea that a board school child might learn in a week to do what used to be done only by old men after years of study.

Howsoever these things be, in bidding, for the time, good-bye to Prof. Byerly's book, I offer him thanks from a very grateful heart, and in this matter I venture to think that I represent a number of people who wanted such a treatise, and who knew very well the sort of thing they wanted.

JOHN PERRY.

THE "PARAGON" GAS PRODUCER.

Already the prediction of many competent engineers is being fulfilled—that the gas engine will form a useful adjunct to, and ultimately compete largely with, the steam engine for



Roger's "Paragon" Gas Producer.
A, Gas Producer and Steam Generator. B, Gas Cooler and Feed Water Heater. C, Air and Steam Injector.

the generation of electric power. Of the difficulties which surround the use of gas motors of large power we have often spoken, and we are confident that the work which is now being done by first-class engineering firms will go a great way towards their removal. But there is another difficulty, namely, that attending the preparation of the gaseous fuel. Town gas is expensive, and is really not intended to be used as a fuel. The efforts of the gas companies to produce a rich illuminant necessarily conflict with the supply of suitable or cheap gas for use in a mechanical motor. To meet the demand for a cheap gaseous fuel more than one form of water-gas producer have been devised, which generate a non-luminous gas by the passage of steam over or through a fire of coke or anthracite. One of the latest of these inventions is the "Paragon" gas producer, made by Mr. H. J. Rogers, of Watford, which is illustrated in the accompanying diagram.

In introducing this new gas producer to the public the inventor has had in view a saving in space, and a saving of time and attention required in producing gas at a rapid rate for working gas engines of large power. In order to obtain this result he has constructed an apparatus in which the process of gas making and the generation of steam are carried on in the same apparatus, instead of in two separate producers as at present. The gas is made by passing jets of superheated steam and air through incandescent coal or coke. A small generator of about 2ft. 6in. in diameter, and about 5ft. high, will make nearly 1,500ft. of gas per hour at a cost of about 3d. to 4d. per 1,000 cubic feet. There is a special arrangement for clinkering the fire bars without opening the door of the ash-pit, and a special valve has also been constructed of improved design for facilitating the process of feeding the furnace with fuel, and also for examining the state of the fire and for clinkering purposes from above, in addition to that already described for clinkering from below.

Another speciality of this apparatus is that the gas in passing from the producer is cooled by coming in contact with the feed water, which in its turn is heated by coming in contact with the gas on its passage to the gas holders.

INSTITUTION OF ELECTRICAL ENGINEERS.*

MR. ALEXANDER SIEMENS' PRESIDENTIAL ADDRESS.

(Concluded from page 301.)

By far the most important connection between mechanical and electrical engineering is, however, the transmission of power, which has of late acquired so much prominence. If the first stage of the development of the electrical industry was closely connected with telegraphy, the second step may be said to have been taken when electric lighting was introduced, and now it seems that transmission of power is the problem which electrical engineers have to grapple with in the near future. The success of electric tram lines has undoubtedly contributed to direct general attention to the transmission of power by means of electricity; but great care will have to be exercised so as not to start in a direction that can lead to no practical results. Many schemes have been started to introduce electricity as the motive power on the main lines of railway, and to accelerate at the same time the speed of the trains very considerably, even up to 200 miles per hour. It would be rash to say that such a speed will not be attained some day; but, in my opinion, none of these schemes can be carried out on a commercial basis with the means at present at our disposal. Trebling the speed of the trains necessitates a radical alteration in the laying of the permanent way, a thorough reconstruction of the carriages, and demands an amount of power that we have no means at present of estimating accurately, nor have we motors that could produce it with a moderate weight. Even if these obstacles are overcome, the enormous capital outlay could only be justified if a very frequent service was kept up, as in the case of successful electric tramways. In most schemes it is, in fact, proposed to run single carriages at short intervals between important towns; but up till the present time it has not been possible to convince capitalists that such a service would pay, either between Vienna and Buda-Pesth, or between Chicago and St. Louis, which are the most notable instances of such schemes.

Leaving these ambitious projects out of consideration, enough scope remains for the development of electric traction in the country to render a healthy activity in this branch of our industry probable for a number of years; and the report of the Hybrid Committee which sat last year has removed, let us hope, a very serious obstacle to electric traction. As the rules which the Board of Trade has drawn up in accordance with the instructions of this Committee are still under consideration, it would obviously not be in order to criticise the version that has been published; it would, however, be hampering the industry if too many details were too accurately prescribed. In this connection it must not be forgotten that in the past the industries of this country have been developed, to the great advantage of the nation, with very little legislative interference; and it would at present be premature to make the regulations regulating electric traction too stringent, as the working out of this branch of electrical engineering is by no means completed.

Besides traction there is the distribution of power, in which mechanical engineering is of the greatest influence on the successful application of electricity. It is, of course, a purely electrical problem to deliver your current either at a standard voltage, or in a constant quantity, at all points of your network of mains; but the application of the motors to the work they are required to do, and the determination of their dimensions, involve principally mechanical considerations. How much there is still to be done in

* Delivered January 11, 1894.

Digitized by Google

this respect was made apparent during the discussion of Prof. Forbes's Paper on the proposed utilisation of water power at the Niagara Falls. Although the prevailing opinion seemed to be that for transmission to a great distance alternate currents only can be utilised, I believe that of the actually-established long-distance transmissions the greater part are worked with continuous currents. No hard-and-fast rule can apparently be laid down that either the continuous or the alternate current should be preferred in all cases where power has to be transmitted to a distance; and, in judging of the merits of the two systems, the proper conclusion can only be arrived at if the commercial aspect of the case is allowed to decide the question.

The installation of rotary-current motors at the Frankfort Exhibition, driven by the water-power at Lauffen, was undoubtedly an engineering success, and served very well for the purposes of an exhibition; but nobody has attempted to do every-day work on the same lines, for the simple reason that it would have been much cheaper to produce the power in Frankfort by steam engines than pay the commercial interest on the outlay that had been necessary to establish the transmission from Lauffen. The generating plant of this installation is now used for the lighting of Heilbronn, and there are a few other instances where rotary currents are used for long-distance transmissions; but, as I said just now, it would be wrong to generalise by preferring either the one or the other method of transmission in all cases.

Another great field for electric motors is just being opened by their introduction for distributing power in works, with a view of abolishing shafting, leather belts, and other intermediate gearing, and of giving each lathe or other tool an independence that cannot be attained under the present system. A most interesting Paper on this subject was read by M. Castermans before the Society of Engineers in Liége in August, 1892, in which he compares in detail several proposals for distributing power in a new small arms factory, that has since been erected at Herstals. The result he arrived at was that with electrical motors he could exert on the working machines 70 per cent. of the power generated by the main engine, while the next best other method gave only 63 per cent., when the shops were working at their full capacity.

In these problems, again, mechanical engineering questions decide whether the application of electricity is justifiable; and it is quite apparent that an electrical engineer requires to be well versed in a variety of subjects if he wishes to keep in the front rank. Fortunately for our profession, the question of technical education generally has received particular attention during the last quarter of a century; and omitting all reference to other occasions when this subject has been brought before this Institution, I will only remind you of the eloquent address of Prof. Ayrton, which no doubt is still fresh in your memory. It will, therefore, not be necessary for me to repeat his lucid exposition of the transition from the former system of pupilage to the modern one of educating the budding engineers in colleges and their laboratories, which has supplemented, and to a great extent supplanted, the old one. No doubt this altered system of education is capable of producing a class of men who are well adapted to explore the untrodden fields of applied electrical energy, where the problems constantly demand a thorough knowledge of scientific principles; but, in combination with this, an equally extensive acquaintance with practical possibilities is requisite. This most important co-operation of science and practice is essential for all real success, and no doubt it appears to be superfluous to insist on the necessity of bearing this in mind; but a perusal of patent specifications will at once convince you that either the one or the other factor is sadly wanting in many would-be inventors. Years ago it was science that was most conspicuous by its absence in these documents; but in the present time it is very often obvious that the inventor has no clear conception how his invention could be carried out so as to make it useful to mankind, and even fails to see the obvious impossibility of realising his ideas in the way he claims in the specification. As usual, it is very difficult to steer the middle course; and if the scientific man had for years to cry in the wilderness because his pursuits did not receive the proper attention in the education of engineers, it seems now to be the turn of the practical man to warn students that there is something more to be learned besides scientific truths before they can aspire to be recognised as engineers. It has always appeared to me that at school the mental powers should be principally exercised in a way to make them fit for learning, and that at the same time they should become accustomed to the careful consideration of a problem in its various aspects. Although it has been the fashion of late to deprecate the study of Latin and Greek, I am quite certain that the attack is made from quarters where the mental training which the study of these languages entails is not appreciated at its right value, nor is the enormous advantage considered which their knowledge gives in the study of modern languages. After the mental powers have been prepared in this way, it is of no great consequence whether most of the details of the school teaching are speedily forgotten or not; the essential point is that the student should have acquired a good method of learning, so as assimilate to the best advantage the course of training he attends at college. While the teaching at school has a general character and embraces chiefly subjects that ought to be known to all classes, at college the various professions are differentiated, and in each branch the students learn the general principles that ought to govern them in their future career. Formerly it was possible to let the course of scientific studies embrace all that was known in any particular branch; in fact, the general principles and the interdependence of the various branches were not, and partly are not yet, properly understood. To attempt a similar course at the present time is simply impossible, and the danger that has to be avoided in our scientific colleges is the tendency to teach our profession too much in detail. Besides overwhelming the professors with work, such a course is apt to create in the students the conviction that on leaving college with a first-class certificate they know all that can possibly be known, and that anything that does not fit in with theory of their pet professor must necessarily be condemned.

A fault into which young men are liable to fall, when they come full of honours from college, is that they consider the passing through workshops beneath their dignity, especially when they have attended for the prescribed time in the workshop of the college. They quite forget that the practical conditions that prevail in works where machinery is made for sale differ entirely from those of a laboratory, where the only aim is to give the students an opportunity of acquiring manual skill.

Another class of students commences practical work with the greatest interest, and the fixed determination to introduce with all possible speed the various improvements which the difference of the practical work with which they come in contact from the teaching at college suggests to them. On all these students it cannot be impressed too much that the practical training is of quite as much importance as the scientific course at college; in fact, in most cases the conclusions of pure science have to be modified by practical considerations before a useful application of science can be produced.

For this reason it is highly desirable that the teaching at engineering colleges should be confined to general principles, as far as the applications of science are concerned, but that the students should become thoroughly well acquainted with the mental tools that are used in scientific investigations, such as mathematics, the general principles of chemistry, and of the branches of natural philosophy. While the student is trained afterwards in practical work, he has time to select what special branch of the profession he wishes to devote his life to, and no doubt he will find that his college studies have to be supplemented by reading up the various technical works referring more particularly to the selected branch. If he has been able to acquire a certain knowledge of modern languages, he will find his labours lightened very materially by having a much larger range of literature to select from.

In this respect electrical engineering has been especially fortunate, for it has, more than any other profession, an international character, and this Institution has, from the very commencement, counted among its members distinguished electrical engineers of many nationalities. It is quite true that after a time the principal foreign nations formed their own electrical institutions; but the international character of the profession has been kept up by the congresses which have met from time to time with a view of regulating electrical matters of international importance.

At the official congress which met last year at Chicago, an international system of units of measurement has been settled, or, rather, readjusted, for the electrical engineers have from the beginning enjoyed the immense advantage that their units of measurement have been the same in all countries. Not only has this circumstance greatly promoted the inter-communication between the various nations, but the character of the electrical units facilitates the demonstration of the inter-dependence of the various forms of energy, and simplifies the calculations of the engineering profession. If a proof were necessary of the utility of having the same units understood in all civilised countries, it is only necessary to observe the conditions and the tendencies that prevail in other matters of international interest. It is chiefly owing to telegraphy that the conditions of modern life differ so essentially from the state of things before the means of quickly communicating with distant parts were at the service of the community at large. Through the ever-increasing network of telegraph wires all mankind is drawn together, and the mutual reaction of the affairs of distant nations is very well illustrated by the newspapers of all countries vieing with each other to bring the latest news from all parts of our globe, and by the effect this news produces at home. Not only are industrial enterprises greatly aided by the possibility of watching their progress in distant countries as easily as it was formerly possible to follow the fortunes of works in the next county, but the distribution of the commodities of life can be regulated in such a way that an extraordinary demand in one country can be met by an extraordinary supply from another one.

Digitized by Google

Under such conditions of inter-communication it is not to be wondered at that attempts have been made—and, in fact, have been to a great extent successful—for facilitating the intercourse between nations in various directions where an international agreement could do away with existing difficulties. One of the most important international conventions is the Postal Union, into which most nations of our globe have entered, and whose influence is brought home to us every day. In another direction an effort has lately been made to make the mode of reckoning time more uniform, and the result is that Greenwich time has practically been adopted in a great many civilised countries, by making the local time either the same, or differing from Greenwich by one hour or by multiples of an hour. An even more important agreement among many nations has existed now for more than a quarter of a century by their adopting the metrical system of measurement; and it is well worth while seriously to consider the effect of this concerted action on the part of foreign nations, as it forms an ever-increasing obstacle for the successful competition of English manufacturers. An ideal system of measurement should be based on units which can be reproduced at any time and at any place with mathematical precision, and you all know that the metrical system was intended to embody this desirable condition. From various causes, into which I need not enter here, the attempt has failed; even the kilogram does not bear the relationship to the linear units which it originally was intended to have, so that the bases of the metrical system are now an arbitrary metre and an arbitrary kilogram. All the same, its very general adoption has proved a very great convenience, and there is little doubt that the introduction of international electrical units has been accomplished with such facility because they are based on the metrical system.

When we recollect that it was a German professor who suggested the absolute system of measurement, that the British Association first established practical electrical units, that the metrical system is of French origin, and that the electrical system of measurement was elaborated by discussions between engineers and scientific men of all nations at the various congresses, we cannot wonder that a very perfect system has been the outcome, and that its general adoption in all countries has followed without discussions, although the formal recognition may not yet have been pronounced in all cases. Even in this system it has been found necessary to settle one of the units—the ohm—in an arbitrary manner, as it was recognised that for practical purposes it was better to have an arbitrary but fixed standard, than to correct the unit every time that an improvement in methods or in instruments admitted of determining it with greater accuracy than before. It is well worth while to reflect on the lesson which this fact conveys, viz., that, in spite of the earnest endeavours and the painstaking collaboration of most competent men, it has not been possible to follow out in practice the dictates of pure science, but that a compromise was found to be inevitable.

The conclusions to which this consideration of the influences that have shaped the course of electrical engineering leads us, may well awake in us the hope of an ever-increasing activity and of an ever-growing importance of the applications of electricity; but we must not forget that we can only succeed if we understand how to adapt our work to practical requirements without losing sight of scientific laws. For this reason nothing can further the interests of our profession more than a free and frequent interchange of ideas between the engineers, who carry out the practical applications, and the scientific men, who investigate the nature of electricity. In the past this Institution has been the arena in which many subjects have thus been discussed to the advantage of everybody concerned; and it is the duty of all its members to contribute, either by reading Papers or by criticising those submitted by others, to the development and to the ever-increasing importance of the Electrical Engineers.

TECHNICAL EDUCATION.*

It is now fully admitted that the education of an engineer should be twofold, and that neither instruction in theory nor experience in practical work should be omitted from it. This point is so fully conceded that it is quite unnecessary to elaborate it. But there is still great diversity of opinion as to the method of carrying out the partition, and probably the conflicting claims of the college and the workshop will never be settled. The years at the command of the neophyte do not suffice for him to learn all that is to be acquired in either department of his professional knowledge, and hence at each step in his career he finds matter for regret that he did not devote more time to the particular branch with which he is dealing. To-day he realises that with greater mathematical skill and a deeper knowledge of physics he could greatly lighten his labour, and to-morrow he sees that a wider experience in practical construction would have saved him from mistake and from loss of reputation. Thus his opinion of the respective values of theory and practice is swayed from side to side by the exigencies of his work, at least until a lengthened acquaintance with his profession has furnished more ample materials for judgment. Possibly by that time the conditions of science and of teaching have so far altered as to vitiate the premises upon which he bases his conclusions.

Temperament again, acts very curiously on the judgment; from the same facts two men of different natures will arrive at diametrically opposite conclusions. The sensitive conscientious man, full of anxiety for his client's interests, will have his pride in a piece of fairly successful work clouded by the reflection that he could have done it better if his education had been different. On the other hand, the gaze of the thick-skinned, self-sufficient individual rivets itself on those features in which the class of knowledge in which he is most proficient is displayed, and he congratulates himself, and the world in general, that he never wasted much of his time in the class-room or the workshop, as the case may be. Both these attitudes of mind may, and do, lead to error. The truth is only arrived at by a due weighing of the advantages of a certain type of education over its disadvantages, and as there are neither balances nor standard weights for the purpose, it is almost impossible to attain an exact result.

Without going to the length of indorsing the cynical definition that "Youth is a mistake and old age a regret," it must be conceded that later years always show that many of our early efforts were misdirected, and that this is true of education as of other things. It cannot be otherwise. A youth's ignorance of his mental nature is usually only exceeded by his want of knowledge of the actual conditions he will have to meet in the world. Under these circumstances he chooses a calling (let us say that of an engineer), or it is chosen for him by a parent who probably knows less of the latent powers of his mind than he does himself. If he comes of well-to-do people, he goes through the accepted course of study and apprenticeship, and then fares him forth, like a knight-errant, to win fame and fortune in the battle of life. He should not fail for want of weapons, for he literally bristles with them, like the villain in a transpontine drama. Each branch of engineering he has studied under a separate professor, while he has acquired practical knowledge and manual dexterity in some important manufacturing establishment. Now, if the youth have in him the makings of a first-class engineer, he has probably followed a satisfactory course. His ability will soon be recognised, and he will be able to guide and shape his career along the lines which best suit his temperament and utilise his acquired knowledge. But if he fall a good deal short of this, as nine out of ten must do, and, instead of being able to choose his path in life, has to take what presents itself, or, worse still, finds he has made a mistake in adopting his calling—no unusual occurrence—much of his highly-specialised knowledge becomes almost useless, and he has to recommence his education under less advantageous conditions.

Seeing, then, that there are two highly uncertain factors to be taken account of by every young man—namely, his own mental powers and the opportunities he may find or make for himself in the professional world—it becomes a question how far it is wise for him to adopt a system of education that is based on the assumption that he is to be a leading light in Great George-street, and sit at the council table of the Institution. Surely it would be better for him to aim rather at cultivating the powers of his mind than at acquiring detailed knowledge. This is a view we have advocated for years, and we were glad to find it confirmed last week by Mr. Alexander Siemens, in his Presidential Address to the Institution of Electrical Engineers. Mr. Siemens is well qualified to stand between the professors and the so-called practical men, and to divide the educational territory between them. He is the representative, in England, of the greatest engineering family ever known. Not only were Dr. Werner von Siemens and Sir William Siemens leading engineers in the sense that they were the heads of immense establishments, and that they devised and directed important works of great magnitude, but they were also acknowledged leaders of science, directing and moulding the opinions of their time in subjects quite outside of their professional duties. Probably few men have made greater use of science for utilitarian purposes than they, or owed more to it in a pecuniary sense, and yet they were constantly making excursions into subjects that did not afford, and could not furnish, any return except intellectual pleasure. Apart from family traditions, however, Mr. Alex. Siemens may claim to know more than most engineers of the influences of a scientific education. In a German university, and later in the German Army, he became acquainted with two of the most elaborate systems of education that exist. Further, as the head of a large industrial undertaking, employing an extensive staff, which must be constantly recruited with new blood, he has before him men trained in many different ways, and he can compare the effects of the different systems. As the result of his experience he says:—"It is highly desirable that the teaching at engineering colleges should be confined to general

Digitized by Google

principles as far as the applications of science are concerned, and that the student should become thoroughly well acquainted with the mental tools that are used in scientific investigations, such as mathematics, the general principles of chemistry, and of the branches of natural philosophy." It is only right to add that he does not arrive at this conclusion by the same train of reasoning as ourselves. He says:—"In most cases the conclusions of pure science have to be modified by practical considerations before a useful application of science can be produced." The two sentences taken together are a severe criticism on professorial engineering, and the implication is much more serious than anything we have ever written on this subject.

Before the college comes the school, and an attempt is often made by anxious parents to mould the course of instruction so as to comprise the elements of professional knowledge. In doing this they strike at the very roots of a boy's mental growth. While the intellect is yet tender, they ante-date the narrowing, cramping effect of a specialised calling. Just as the modern system of construction produces workmen who can do one thing only, and are without the slightest claim to the appellation of mechanics, so does a severely-specialised education turn out men capable of only few ideas, and those but simple. The school is, or should be, the gymnasium of the mind; in it every faculty should be trained by exercise into fair proportions and healthy growth. Symmetry, and not hypertrophy, is what is to be aimed at—the co-ordinate action of the various branches of the intellect under the control of the disciplined will. We never ask what economic results the athlete has effected during his training, how much material he has transported, or how much timber he has sawn. It is to the future we look for the fruits of his exercises and self-denial. It is equally absurd to judge of a boy's progress by his acquired knowledge. If he have learned to meet and attack a problem, or a hitherto unknown science, with a skill and determination like that with which the trained fencer faces a new antagonist, his education is of the highest order, even if he have less useful knowledge than the "third standard" boy of the Board School. As Mr. Siemens put it: "It has always appeared to me that at school the mental powers should be principally exercised in a way to make them fit for learning, and that at the same time they should become accustomed to the careful consideration of a problem in its various aspects. . . . After the mental powers have been prepared in this way, it is of no great consequence whether most of the details of the school teaching are speedily forgotten or not; the essential point is that the student should have acquired a good method of learning, so as to assimilate to the best advantage the course of training he attends at college."

Though the forgetting of school learning may be relatively unimportant, it is, we fear, the sign of inefficient teaching. There are few powers of the mind more important than memory. Without it the student is continually spinning a rope of something that is little better than sand. To the man of the world a good memory is of the utmost importance, as the bulk of his knowledge is not to be found in text-books, and much of it cannot even be written in his notes. A good memory is absolutely necessary for correct reasoning and rapid decisions. How strong and capable we should all feel if the whole that we have ever learned were at our "fingers' ends!" Even if we knew where to find the half of it, we should be the gainers. The value of memory is only second to that of perception, and hence its acquisition should rank high in the schoolmaster's scale. Its cultivation involves its exercise, and, therefore, the process of rendering the mind retentive must store it with knowledge. A trained memory cannot coexist with an empty head. It is not merely retentiveness, however, that the teacher should aim at developing. Of equal importance is an orderly method of thinking. If it be the habit of the mind to arrange all the facts of a series in connected natural order, it ceases to be a labour to remember them. The first suggests the second, the second hints the third, and so on in easy sequence through the entire train. The fact wanted may be the last of the chain, but, like Fair Rosamund in the recesses of her intricate bower, its discovery becomes certain from the moment that the clue is found.

The necessity of great attention being paid to the training of the memory of boys is rendered more urgent by the fact that immediately they leave school many influences combine to destroy, or at any rate to pervert, its operation. Firstly, there is the system of note-taking at professor's lectures. This is often carried to such an extent that the whole attention is concentrated on the mechanical operation of putting the spoken words on to paper while their sense never reaches the brain. The effort to understand, which is the best aid to remembering, is not made; afterwards the subject is read up from the note-book, but the mental impression is less sharp than if derived from the teacher's lips, aided by his gestures and facial expression. Again, the system of cramming cultivates a temporary or spurious memory, which, while most valuable for the passing of examinations, and also for some other purposes, weakens the permanent memory. It is surprising what a load the brain may be made to carry if it have the assurance that the cargo may be jettisoned at an early date. This is seen in the case of barristers, who will in a short time obtain complete mastery over an intricate case, and will forget every detail of it with equal celerity. Such a habit, however, cannot be indulged in with impunity, and before it begins every care should be taken to lay up a store of mental strength to withstand its debilitating effects.

Mr. Siemens recommends the study of Latin and Greek. He says:—"I am quite certain that the mental training which the study of these languages entails is not appreciated at its right value" [by those who deprecate it], "nor is the enormous advantage considered which their knowledge gives in the study of modern languages." We fully agree that one who has not undergone the stern mental discipline required to obtain a facility in the composition of Greek and Latin verse has no idea of its value. A bright, but not over industrious, schoolboy, once asked, in our hearing, "What use is Latin in making steam engines?" and got, as reply, the question, "What use is a grindstone for drilling a hole?" The lad saw the point at once, and replied, "Oh, I suppose you mean Latin sharpens one's mental tools." The truth of this has been demonstrated through many generations. But, with new studies opening out on all sides, it is in the highest degree probable that there may be some of an equal value from an educational point of view, and which would bring a more direct advantage. We have heard the plea that Latin aids the study of modern languages many times before, but the fact remains that all well-educated Englishmen in the past were thoroughly taught the classics, and that only one in a hundred could speak any language but his own. It is worth while trying if we cannot grind our brains on living tongues. We fancy that a German treatise on "Mysticism," or on "The Relation of the Finite to the Infinite," would afford as much material for painstaking research and methodical labour as most people need, while the cultivation of readiness of wit and of an incisive style might be well effected by the study of French classics. Whether this be so or not, a very serious effort should be made to determine whether other studies cannot be made of equal mental value with Latin and Greek. In saying this, we are not contradicting our contention that the great object of the school period is to learn how to learn, and that the kind and amount of knowledge acquired are secondary. But life, especially educational life, is short, and secondary results are too important to be entirely overlooked. We fully believe that it is possible to arrange a curriculum in which the dead languages bear only a moderate part, and yet which shall be potent for cultivating all the faculties of the mind, and bringing them into full and healthy activity. At the same time such a course would have the added advantage that it would open a world of delights to those undergoing it. Not only would it unlock for them the literatures of one or more European countries, but the whole universe would bear a different meaning from that which it presents to the youth who has spent nearly all his time on the classics. Science would show them that the world was full of order and symmetry, bidding them admire the wonder and beauty and mystery of every object surrounding them. History, fiction, and the drama would open to them the most interesting and profitable of all studies—man—while drawing and music would cultivate their artistic perceptions. Except in the case of the inveterate dullard, some one of these subjects must have awakened attention and roused enthusiasm, which it must be confessed Latin and Greek seldom do, and there is no aid to mental culture equal to enthusiasm. At present educational systems are in a state of transition, but it is quite easy to see, firstly, that classics are regarded with decreasing interest, and, secondly, that their study will never cease to form some part of a liberal course. The uncertain point is how much attention ought to be bestowed upon them.

THE BOARD OF TRADE ELECTRIC TRAMWAY REGULATIONS.

The usual Council and Committee meetings of the Tramways Institute were held at the offices of the Institute, at 18, Eldon-street, E.C., on Thursday last week, to consider various matters, the agenda including a discussion on the draft electric tramway regulations recently issued by the Board of Trade.*

Mr. CARRUTHERS WAIN, the President of the Institute, occupied the chair, and in opening the proceedings said: I am quite sure you will all learn with regret of the death of Mr. Reckenzaun, one of our members and a well-known electrician.

Proceeding to the discussion of the electric clauses Joint-Committee's report, and the Board of Trade regulations,

The CHAIRMAN said that the question to be discussed in regard to these electric clauses was a very simple one. He had a report of the proceedings before him. The Institute appeared by counsel before the Joint-Committee, and the Joint-Committee reported, and that report was a favourable one for electric traction. That was followed upon by the

* See *The Electrician*, November 24, 1893, p. 96.

Digitized by Google

Board of Trade with very serious regulations. The document had been sent by the Secretary to every company, and the result had been that they had received certain replies—for instance, the Blackpool Surveyor had written, saying that the whole of the conditions rendered electrical traffic impossible and unworkable. In addition to that, there had been a conference of the Electrical Traction Committee of the London Chamber of Commerce, where all these things were discussed one by one. Mr. Crompton was in the chair, and a deputation from that Committee was formed and waited upon the Board of Trade to know whether they could not afford some explanation of the very ambiguous expressions contained in the regulations, and they would have the pleasure of listening presently to the remarks that would be made by Mr. Sellon on the matter. They were all interested in this subject very much at the present time. The question of electrical traction or some other new form of traction was important, and he felt sure that they would have an interesting discussion on the matter.

Mr. STEPHEN SELLON said that he would commence his observations with what happened at Liverpool. It would be recollected that upon that occasion he read a Paper before the Convention on the question of electric traction, and, although at that time certain tramway companies did not care to consider the question of any different mode of mechanical traction, they all agreed, with a view to the use of electrical traction in the future, that it was as well to safeguard their position, and there was in the result a unanimous vote of confidence. Now as to what had happened since that date. He had appeared before the Board of Trade, by counsel, on behalf of the Institute, but he had, unfortunately, been unable to show to the Committee that the whole of the tramway companies interested in the matter were represented. The great object to be secured by their institution was that the telephone clauses should be abolished from the regulations in reference to the conditions of electric traction. They had had a tremendous amount of labour and trouble in the matter. Mr. Wain, the president, had given leave for the secretary of the institute to circularise every single corporation in the country and every single tramway company in the country that could possibly be interested in the future of electric traction. That circular laid before them showed very clearly that it was desirable that application should be made to the Board of Trade that other clauses should be substituted in lieu of the telephone clauses, and there was also the question of making the Committee's recommendations retrospective. Well, he regretted to say that the answers that he had received to this circular had been very small indeed. It seemed almost impossible to interest the tramway companies of this country in the matter of future traction of the tramways. Whatever they might be ready to do in the future they replied now they "were not ready to discuss the matter at the present moment," and so on. He regretted that they showed such a small amount of common sense. He had been working hard for a considerable time in endeavouring to obtain the abolition of these telephone clauses. Mr. Alfred Dickenson, who was an authority upon these matters, would tell them that it was absolutely impossible to maintain the conditions of electric traction under the regulations that these clauses sought to impose. Having alluded to the present condition of the Glasgow Tramway Company, he said that, having discussed the question of the telephone clauses, they now came to the question of the report of the Joint Committee and the regulations of the Board of Trade. The Board of Trade informed him that they would only promote a general Act to abolish these old telephone clauses, and make the ruling of the Committee retrospective upon the district showing that there was a universal concensus of opinion that these clauses should be struck out. Now he could only reply to the Board of Trade that the support that he had received from the tramway companies was very small in comparison to the amount of the tramway's interest, and therefore the Board of Trade would not agree to bring in a Bill to abolish the clause at the present moment. Well, they had had a good deal of discussion at the Conference that day. They had discussed questions of paving, traction, and the Tramways Act of 1870 and its hardships. They had also discussed the question as between tramway companies and Corporations, and in nearly all cases the only answer that they could say to them was, "Serve you right." It would be the same in regard to the question of the future of electric traction if the tramway companies did not combine together against the hardships that it was sought to impose upon them in this direction. He then proceeded to refer to the accusations that had been brought against tramway companies working with electricity that they disturbed the telephone wires, that they upset railway signalling, and did damage to the mains of the gas and water companies. The result of the sitting of the Joint Committee in regard to the telephone companies contentions, was that they had stated that the telephone companies had their own remedy, which was a very simple one. They could adopt the duplicate wire system. As to railway signalling, the Joint Committee saw a little more difficulty there, but fortunately there was this point that if it was dangerous for them that the wires should be near, it was equally dangerous in the case of the railway companies' wires that might themselves be affected by a storm or electrical disturbance. After alluding to the satisfactory working of the South Staffordshire system, he said that as regarded the complaints of gas and water companies, they might equally well be directed against the wires of the telephone companies themselves. He then proceeded to stigmatise in very strong terms the report issued by the Board of Trade in this matter. The Committee, he said, sat for 14 days, and the report of that Committee really said that under no conditions need they trouble about the telephone companies, they must protect themselves; and now the Board of Trade by its draft regulations made the report of the Joint Committee unworkable. Really what they required before they could understand the regulations of the Board of Trade was that the Board of Trade should send the key to them. He asked the Board of Trade for further information, and the Board of Trade replied to him asking him to kindly point out the matters upon which he disagreed with the regulations. He replied that he disagreed with them all. Mr. Sellon then proceeded to pass certain severe strictures upon the National Telephone Company, and said that it would be remembered that the counsel stated before the Committee that the telephone was "an instrument for the purpose of hearing every other person's voice except the one that you wanted to listen to." It was claimed by the National Telephone Company that the telephonic system in London was quite as good as any other town—Berlin, for instance; but in Berlin, he would like to point out, the telephones were under the control of the Government, and if an unfortunate subscriber complained to the Government that his telephone did not work, their only answer was to send a man to cut it off, which was not what they required of the National Telephone Company. What they desired to do, he said, was to protect the telephone interest against the tramway interest. After again alluding in strong terms to the National Telephone Company and its management, he said that their object that day was to consider the tramways interest. He simply asked that they would all assist him in the formation of a committee for the protection of the tramway's interest, so that they might go to the Board of Trade and show that the tramway companies were really interested in this matter of electrical traction as against telephone companies. He desired to state that out of about 90 tramway companies in England only some 10 of them had got electric powers, and he supposed that for that reason the other 80 did not reply to the letter that was circulated.

Mr. WAUGH said he knew of companies that wanted to change their systems for electrical systems, but they could not do it.

The CHAIRMAN: Why?

Mr. WAUGH: Because they cannot raise the money.

Mr. SELLON said that he believed the reason why money could not be raised for these electrical systems to be tried was that, as in the case of the North Metropolitan Company, there was a clause in the Act by which they could be compelled to remove the electrical installation within a week.

Mr. ELLIOT: 24 hours, in one instance.

Mr. SELLON said that he believed Mr. Preece, if he had his way would insist upon a metallic return throughout with regard to the telephones.

Mr. PLATT remarked that he thought it the duty of every tramway company to subscribe the £1. 1s. Mr. Sellon had asked for towards his expenses.

Mr. A. DICKINSON said that he had listened with very great attention to the remarks of Mr. Sellon, and he thought that a great deal of the want of support on the part of the tramway companies was due to their lack of knowledge in electrical matters. It was really ignorance that accounted for their apathy. It was ignorance on the part of tramways and corporations that was the fault. However, the draft regulations of the Board of Trade were as difficult to understand as to work under them. Clause 10 was impracticable.

"The insulation of the line and of the return when insulated, and of all feeders and other conductors, shall be so maintained that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before or after the hours of running when the line is fully charged. If at any time it should be found that the leakage current exceeds one-tenth of an ampere per mile of tramway, the running of the cars shall be stopped until the leak has been localised and removed."

Having read the clause he observed that the Board of Trade said that a company should not work with one hundredth of an ampere leakage he stated that he had worked with 300 amperes leakage for a whole day (laughter). He asserted that if the regulations were reversed and made to state that they should not work unless there was a leakage of 300 amperes, the majority of tramway men would not be any the wiser. He did not think he was throwing any slur upon his friend, the secretary, in supposing he did not understand what that meant. He hoped his words would not be misunderstood, but he maintained it was utterly useless to circulate such reports amongst tramway companies, and what he desired to suggest was that they should form a technical committee of that Institute to consider and report upon such electrical matters.

Mr. SELLON quite agreed with this view, and said that the fact that counsel appeared in the matter—and won the day—was solely due to the interest shown in the question by the electrical traction companies who instructed the counsel, and not to the tramway companies.

Mr. DICKINSON: It is a great shame.

Mr. ELLIOT: What can you do if people will not support you?

The CHAIRMAN: Well, it certainly seems that the thing to be done is to appoint a committee—a small committee is always better than a large one—and I will suggest, subject to any amendment that may be moved, "That Messrs. Stephen Sellon, A. P. Smith, Alfred Dickinson, and John Waugh, with the President, be appointed a committee to draw up an explanation of the draft regulations submitted by the Board of Trade, and circulate it amongst the various tramway companies associated with the Institute." That I think will be a practical issue of the subject discussed to-day.

Mr. WAUGH: I second that.

Mr. WHITING asked if the Committee would issue amended regulations.

The CHAIRMAN: Yes; certainly. The old and the new in parallel columns.

A MEMBER suggested that Mr. Hesketh, the borough surveyor at Blackpool, should be added to the committee, as that was a tramway with electrical powers.

The CHAIRMAN: Certainly. Well, I will move the resolution in this form, "That a committee, consisting of the following gentlemen, Messrs. Stephen Sellon, A. P. Smith, Alfred Dickinson, John Waugh, W. Hesketh

Digitized by Google

and the President be appointed to deal with the electrical clauses and the draft regulations submitted by the Board of Trade, and to take such steps as they may think desirable in the interests of the tramway companies."

Mr. WAUGH seconded the motion, which was carried.

After some further discussion, a vote of thanks was accorded to the President, and the proceedings terminated.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

Mr. Hannay resumed at Marlborough-street on Monday last the hearing of the charges of conspiracy to defraud made against Cornelius Bennett Harness, of the Medical Battery Company, J. M. M'Cully, and C. B. Hellier.

ALICE JANE BEATTIE said she was a member of the Royal British Nursing Association, and held a diploma from the London Obstetrical Society. In August, 1892, she had a severe illness, and for the consequent extreme exhaustion she consulted seven or eight medical men, who for the latter part of the time did her no good. Dr. Heywood Smith recommended her to go to 52, Oxford-street. She paid a reduced fee of £5 for treatment for three months. The fee was reduced because she belonged to the nursing profession. She was treated by Dr. Laird and attended by Nurse Higgins. She had a belt which she wore, and after three months she was able to resume her duties as a nurse. She was quite satisfied that the treatment she received at Oxford-street cured her. She volunteered to give evidence in the case.

Cross-examined by Mr. Gollan: She did not go to Oxford-street dressed as a nurse. She paid £5 and got a receipt. The nurse she saw at the Medical Battery Company did not diagnose her complaint. She was treated with massage and electricity, and sat on the statical chair, and used to visit the place about twice a week. She wore the belt all through the day for three months. Occasionally during that period she left off wearing it. She wore it next to her skin, and it did not chafe her in any way. The sum first mentioned for the treatment was from £12 12s. She asked to have the fee reduced as she was a nurse and had suffered from a long and expensive illness.

Similar evidence was given by Miss JESSIE BOND, the actress, who stated that in October, 1890, she was suffering from nervous exhaustion, weakness, and loss of voice. She paid 50 guineas for the treatment, which lasted over 12 months. For that sum she was, in addition, supplied with two belts. She thought she went to the establishment quite 50 times.

Mrs. JANE CRAWSHAW, daughter of Colonel Mountjoy Martin, of the 2nd Life Guards, also gave evidence in the same sense. She wished to pay for the treatment, but Mr. Harness declined to take any fee, saying that he had derived great benefit from the persons she had recommended to him, and that she could always have treatment without payment.

M'CULLY said he wished to crave the indulgence of the magistrate for a few moments. The case had been before the Court 14 times, and there was not a tittle of evidence against him. He could hold his head up before the whole world, and asked in the name of all that was English and right that he should be liberated.

Mr. HANNAY said he could not then allow such a course. Probably the whole charge would be disposed of when the case again came on for hearing, and most likely he would then give his decision one way or the other.

The further hearing of the case was adjourned till next Wednesday.

Sheffield Café Company v. Bakewell.

An action which involved a novel point of patent law was heard before his Honour Judge Ellison at the Sheffield County Court on Friday last. A claim was made by the Sheffield Café Company against William Bakewell, electrical engineer, of Shortridge-street, Attercliffe, to recover £10 damages. The claim was originally for £17. 18s., £9. 10s. for 76 lamps given up to the Edison Swan Company; £5. 5s., charges of Messrs. Ashurst, Morris, Crisp, and Co., solicitors to the company; and £3. 3s., charges of Messrs. Clegg and Sons, solicitors, of Sheffield. Of this sum £7. 8s. was abandoned, and the claim reduced to £10. Mr. W. E. Clegg appeared for the Café Company, and Mr. Arthur Neal for the defence.

Mr. CLEGG, in opening the case, said that his clients sued to recover damages by reason of the defendant having wrongfully supplied to them a number of electric lamps which were infringements of valid patents. By his having done this plaintiffs were prevented from using the lamps and put to expense. The case should have come on on November 23rd, but some negotiations had taken place with the result that the original claim of £17. 18s. had been reduced to £10. The facts were somewhat peculiar. It appeared that some time in June, 1892, defendant saw plaintiffs' manager, and said he had an incandescent lamp of German origin equal to the one the company were using. This he could sell to the company at 2s. 4d. In consequence of that statement orders were given to him from time to time until he had supplied to the company some 140 lamps, the last being delivered on April 17, 1893. On May 1, 1893, the plaintiffs received a letter from Messrs. Ashurst, Morris, Crisp, and Co., solicitors to the Edison-Swan Company, in consequence of which they communicated with the defendant. The letter they received pointed out that all the incandescent lamps made by the Edison-Swan Company were marked with their name, and any such lamps not so marked were an infringement of their patent, which comprised every form of electric incandescent lamp. Defendant when this letter was read to him said he thought that the patent for these lamps had expired, and that he had a right to sell them. Upon further investigation plaintiffs found that the patent had not expired, and that it had consequently been infringed by them. They accordingly gave up to the Edison-Swan Company some 83 lamps and paid the solicitors their charges rather than run the risk of an injunction and damages granted against them. Defendant it appeared had also to make terms with the Edison-Swan Company. Plaintiffs now sought to recover from Mr. Bakewell the money paid for a consideration which had failed. The latter had offered to refit the café with Edison-Swan lamps at the expense of the plaintiffs, giving his services for nothing, but declined to pay any damages.

In reply to a question from the Bench, Mr. NEAL said that most of the facts were admitted, so that it would be unnecessary to call many witnesses.

Mr. WHITEHEAD, general manager of the plaintiff company, was subjected to cross-examination by Mr. Neal. He stated that the average life of these incandescent lamps would be, he thought, less than 18 months. Some of the lamps given up to the Edison-Swan Company had been in use for some time, but others were quite new. It was not a fact that defendant had given him the choice of two kinds of lamps—the Edison-Swan and the Zurich. The former they were already using, so that it was not likely he would do so.

Mr. BAKEWELL, called by Mr. Neal, stated that he had submitted two lamps to the plaintiffs' manager, and that the latter chose the cheaper.

By Mr. CLEGG: He styled himself an electrical engineer, yet he did not know that these Zurich lamps were an infringement of the Edison-Swan patent. If Mr. Clegg had had any experience in this matter he would know that there were a great many big electric companies who had made the same mistake, and had had to suffer for it.

Mr. NEAL: I do not think there is any legal principle which will affect this case.

His HONOUR: There is that principle of selling an article injurious to the purchaser, and the question is whether an article which is an infringement of a patent is not an injurious article in the hands of a person who is not entitled to use it.

Mr. NEAL: There is no evidence that this lamp was an infringement of the patent laws.

Mr. CLEGG: I thought that was admitted. If my friend is going to raise that point I can soon get someone down from the Edison-Swan Company who will put the matter beyond all doubt.

Mr. NEAL said that perhaps that point would not arise. His client, on the evidence as it stood, was equally an innocent person with the plaintiff. He had sworn that he had shown to Mr. Whitehead two lamps, and that Mr. Whitehead chose the cheaper one. If there was any *tort* at all committed it was committed then, and Mr. Whitehead was a party to it. Both of them were infringing the right of a third party, and if so neither was entitled to indemnity from the other.

His HONOUR asked where was the warranty on which the plaintiff depended.

Mr. CLEGG contended that defendant was an electrical engineer, who held himself out to the public as a person well acquainted with everything connected with electricity. That being so, it was his duty to know the state of patents with regard to electric lamps, and he held out an implied warranty that he had a right to sell these lamps, and that the purchaser would be right in using them.

His HONOUR: It may be there is no infringement.

Mr. CLEGG: I understood my friend to admit that. You see his client himself admitted it by paying a sum of money to the company.

Mr. NEAL: Oh, no; I do not admit it. We paid costs in order to avoid an expensive law suit.

His HONOUR: I think it would be better if the case stood over for a fortnight. I shall then have time to look up the law on the subject.

The action was accordingly adjourned.

CORRESPONDENCE.

INSULATION RESISTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your very interesting articles on insulation resistance there is, I notice, but one slight mention of special standards of insulation for alternating currents. Now, if we adopt Mr. Human's series of standards for different voltages, we ought, as a logical sequence, to take into consideration the maximum E.M.F. of an alternating current, and not the square root of the mean square; and as the former is approximately 1·4 times the latter, we ought to raise the minimum values of insulation resistance for any given number of lamps lighted by alternating currents to 50 per cent. above the minimum values given for the same number of lamps lighted by continuous currents.

Mr. Human's plan is extremely useful, though, in my opinion, the standard he has selected is too high; half the value would, as you suggest, give a safe and practical series of figures.

With regard to the question of moisture, it would be an element of safety to insist that no test be made when the relative humidity of the air is above a certain fixed percentage, and that the hygrometer form part of the testing office apparatus.—Yours, &c., CHAS. A. GAWTHORP.

January 19, 1894.

EJECTOR CONDENSERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Our attention has been drawn to a very interesting article on page 267 of your issue of January 12th, concerning the Willans engines, where mention is made of the great and deserved success of their exhibit at the late Chicago Exhibition. As a considerable portion of the technical press has spoken in terms of unqualified praise of the performance of these engines in America, it may interest some of your readers to know that a new departure was made in regard to the condensing plant by fitting the 360-H.P. and the 135-H.P. engines with our patent ejector condensers. Considering the prejudice which exists in many engineering circles concerning this class of condenser, it is satisfactory to know that no hitch was experienced by adopting this—as many would consider—somewhat daring innovation, the deservedly-high reputation of the Willans engines being sustained in this instance as in all others.—Yours, &c.,

35, Queen Victoria-street, T. LEDWARD AND Co.
London, E.C., January 19, 1894.

LIGHTNING EXPRESS RAILWAY SCHEME.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The remarks made in his Presidential address by Mr. Siemens on the subject of high-speed electric railways appear to have produced the impression among many that such schemes are far without the bounds of practical engineering. He does not discriminate; he includes all rapid transit schemes under one common ban.

Now, on November 9th and 11th last, shortly after the announcement was published that we had undertaken to develop the experimental work in connection with Mr. Behr's lightning express single-rail railway scheme, Mr. Siemens signed and addressed to this Company letters in which he offered to supply our requirements as regards the electrical portion of the work, and to place the experience of his Company at our service.

We think, therefore, in view of such public pronouncement as that referred to that we are justified in publicly calling Mr. Siemens' attention to the discrepancy between the expressions of the speech and of the letters.—Yours, &c.,

THE THAMES IRON WORKS AND SHIP BUILDING COMPANY (LIMITED),
C. E. GROVE, Electrical Engineer.

January 23, 1894.

THE BRIGHTON AND HOVE COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am glad to notice in one of your leaderettes of the last issue of *The Electrician* a retraction of your statement in regard to the value of our plant; but while appreciating your disavowal of any intention to undervalue our machinery, or to assail the prestige of the manufacturers, I would like to draw your attention to the fact that the tenor of your explanation somewhat confuses the matter. In expressing your regret, you mention that you "referred to the Corporation offer," which offer, you proceed to state, was "to purchase the Company's *undertaking* for the sum of £5,000. . . ." I may point out to you that our arrangement with the Corporation is for the disposal to them of our *goodwill only*, and it practically amounts to this, that the Corporation are paying £5,000 compensation to the Company in consideration of their ceasing to supply current within the Borough of Brighton. This arrangement does not come into effect until September 30th of this year.—Yours, &c., G. W. SPENCER HAWES,

Brighton, The Brighton and Hove Electric
January 24, 1894. Light Company (Limited).

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES' DIRECTORY AND HANDBOOK" is in preparation, and will shortly be published. *New names, alterations of addresses, &c., should be sent in at once.* Full printed particulars can be obtained, post free, from "The Publisher," *Electrician* Office.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) Prospectus on application to the Publisher.

TENDERS INVITED.—Tenders are required for an electric light installation at the Chancelot Roller Flour Mills, Edinburgh, specifications for which can be obtained of the Secretary, Scottish Co-operative Wholesale Society (Limited), 119, Paisley-road, Glasgow.

——— Tenders are invited for the supply and erection of an electric lighting plant for lighting a portion of the left side of the port of Rouen. Specifications and particulars may be obtained from M. Cadart, engineer, 52, Quai du Mont Riboudet, Rouen, and tenders must be sent in by March 12th.

BANKRUPTCY.—At the Salford County Court, on Friday, Mr. Walter Rowbotham, electrical engineer, of Salford, who became a bankrupt in 1890, applied for his discharge, which was granted, subject to a suspension for three months.

——— Mr. Osmond Yeadon Rhodes, trading at 130, Albion-street, Leeds, as the Yorkshire Electric Engineering Company, has filed a deed of assignment. The liabilities are given at £236, and the assets at £80.

——— The statement of affairs prepared by Mr. Free Chilton, electric, cycle, and general engineer, Luton, shows liabilities £256, and assets £12. The debtor ascribes his failure to the loss of an action for slander brought against him, which cost him over £200.

LIQUIDATIONS.—Two petitions for the compulsory winding-up of Elmore's Patent Foreign and Colonial Copper Depositing Company (Limited) came before Mr. Justice Wright, in the Chancery Division, on Wednesday, but were, by consent, allowed to stand over again, Mr. Assheton Cross, who appeared for the Company, stating that during the proposed interval it was hoped that a satisfactory arrangement would be come to. Counsel for the petitioners expressed their belief that the Company was making a *bonâ fide* endeavour to meet its liabilities. The petition was therefore allowed to stand over, with leave to the petitioners to apply to the Court in the event of dissatisfaction with the Company's proceedings.

——— A petition has been presented for the winding up of R. Bolton and Co. (Limited), and is down for hearing on the 31st inst.

Digitized by Google

Removal Notice.—Mr. G. H. Congdon has removed from Palace Chambers, Westminster, to Trafalgar House, Great Newport-street, W.C.

Site for Disposal.—Mr. F. Hazell, land agent, 117, Victoria-street, London, S.W., has extensive freehold wharf land between Albert and Battersea Bridges, London, with 400ft. frontage to a dock, to be let or sold.

Voltmeters.—Mr. R. W. Paul reports that during the past year a large number of Ayrton and Mather electrostatic voltmeters (a description of which appeared in our issue of June 9th last) have been manufactured and supplied to the principal electric lighting companies, amongst which are the Metropolitan, City of London, London Electric, Brush, and Laing, Wharton and Down Companies, as well as the Bristol and Derby Corporations, and several foreign firms. Mr. Paul announces that he has in process of manufacture instruments on the electrostatic principal for lower readings.

Anderson-Aetna Insulators.—Mr. Robert W. Blackwell, of 39, Victoria-street, Westminster, writes us with regard to the Note relating to the Liége-Herstal electric line which appeared in our last issue but one, and to the letter from Mr. William Dierman which appeared in our last issue, to say that he supplied to the Compagnie Internationale d'Électricité, of Liége, the insulators and suspension devices employed in its erection, and the trolleys with which the cars were fitted. These are all of the "Anderson-Aetna" type, well known in the United States.

Messrs. Crompton and Co.—This firm send us a *résumé* of the work done during 1893, which includes the lighting of the Southampton Docks for the London and South-Western Railway Company, which was carried out on the low-pressure direct-current system, so as to facilitate the use of motors. The installation consists at present of 60 arcs for outside lighting, and 1,000 incandescents for shed lighting. The Great Eastern Railway Company's terminus at Liverpool-street, and the adjoining premises, have been supplied with the electric light by Messrs. Crompton, who are carrying out important alterations in connection with the extensions now in progress. This contract will now number 200 arcs and 7,000 incandescents. The system is the same as that adopted at Southampton, the mains consisting in great part of bare copper strip carried on insulators. A contract for the Bradford Joint-stock Bank comprises twenty warehouse elevators, each driven by a separate motor, the supply being taken from the Bradford mains. Each elevator is constructed to lift 11 cwt. at a speed of 120ft. per minute. The Southend Corporation have entrusted a further order to Messrs. Crompton and Co. for plant required for the electric tramway on the pier, the additions consisting of a second Paxman engine and boiler and three additional cars. At the Crystal Palace the firm have carried out the complete lighting of the main nave and courts, &c., with 90 arcs, the current being supplied from three Crompton dynamos, the lamps being ten in series and three in parallel. This is probably the first time such an arrangement has been successfully carried out—at least, on such an extended scale. For the Hove Electric Lighting Company large extension orders have been received and carried out, both for the Crompton bare system of mains and for the permanent plant and buildings now nearing completion. The Local Authority contracts secured by the firm during the year include orders from the Corporations of Brighton, Dewsbury, Hull, Glasgow, and Lancaster, and from the Hove Commissioners. For the Compagnie Hydro-Electrique, of Antwerp, a contract is in hand for mains for about thirteen miles of streets on the Crompton bare underground system. Large orders for plant have been received from the local lighting companies of Southampton and Oxford, and from the London and India Joint Dock Company for arc lamps for the new lighting arrangements at the Albert Docks. The record for the year also includes a large number of private installations, and the supplying of Crompton plant and apparatus to the agents of the Company at home and abroad.

Messrs. Latimer Clark, Muirhead and Co.—In the Chancery Division on Thursday last an application was made by Mr. Kenyon Parker (on behalf of debenture holders) for the appointment of a Receiver and Manager in the matter of Latimer Clark, Muirhead and Co., electrical engineers. The Company did not oppose, and Mr. Justice Chitty made an order appointing Mr. James Worley receiver and manager, and giving him liberty to borrow or provide a sum not exceeding £4,000 at 5 per cent. for the purpose of carrying on the business of the Company, the sum so borrowed to be in priority of the debentures.

London and Lancashire Electric and General Engineering Company (Limited).—This company report that during the past year, although only the first of its existence, it has been well employed in both mechanical and electrical engineering work. A new system of water-tight tubes and joint boxes, designed by the Company's manager, Mr. C. N. Russell, especially for use in wiring paper mills, breweries, &c., has kept the firm busy. A number of lighting installations have been carried out by the firm during the year.

Telescopic Ladders.—Messrs. J. H. Heathman and Co., of Endell-street, London, W.C., have had on show during the past week a pair of telescopic ladder towers, with bridges 6ft. wide and 26ft. long, to rise and fall, for use in all ceiling work. The ladders can be so used that ceilings can be worked upon from 14ft. to 26ft. high.

Financial Review of Electricity for 1893.—Our contemporary, *Lightning*, in its issue of the 18th inst., gives some interesting figures in a financial review of the past year, from which it will be seen that the capital invested in electric supply undertakings, which at the end of 1892 stood at £4,271,875, was increased during 1893 to £5,264,071, or nearly £1,000,000 sterling for the year.

Electric Ventilating Fans.—Messrs. Ernest Scott and Mountain have just completed a large electrically-driven fan, designed to deliver 30,000 cubic feet of air per minute at a water pressure of 5in. The fan is driven by a 40-E.H.P. Tyne motor running at 700 revolutions per minute, and is intended for use in connection with a new system of induced draught on board steamers and for land boilers. The capacities of the fan have been thoroughly tested, and are stated to have given satisfaction.

English Arc Light Carbons.—We have received the following from the India Rubber, Gutta Percha and Telegraph Works Company (Limited):—

"106, Cannon-street, London, E.C.,
"January 22, 1894.

"Our attention having been drawn to a statement made in several of the electrical newspapers that "all carbons used in England for arc lighting have hitherto been imported from abroad," we should be obliged if you would correct this statement, which is inaccurate. We have been engaged for over fifteen years in the manufacture of carbon rods for electric lighting. These carbons have been made under English patents, and at our works at Silvertown we have a complete plant in daily operation for the production of such carbons for electric lighting.—Yours, &c., "Wm. J. Tyler, Secretary."

Aberystwyth.—Messrs. Bourne and Grant have purchased ground and buildings in Mill-street, and are adapting the premises for electric lighting purposes. The Corporation has, we understand, received the amount incurred in obtaining the Provisional Order.

Bedford.—The Board of Trade have decided that the Urban Sanitary Authority of Bedford has shown no sufficient grounds for handing over the Provisional Order to the Bedford Electric Light Company (Limited).

Berwickshire.—Messrs. Graham and Morton have just completed a contract for the installation of the electric light at Swinton House, Berwickshire, the residence of Mr. John McNab. The contract includes E.P.S. accumulators, and the plant includes a 9-H.P. Crossley gas engine. The contract comprises about 150 incandescents.

Bournemouth.—The Town Council are making an application to the Board of Trade for a licence empowering them to carry on electric lighting works for public purposes. The local electric light Company are not opposing the licence, and the London and South-Western Railway Company have withdrawn the objections of which they had previously given notice.

Bristol.—Messrs. Crompton and Co.'s extensive installation of the electric light at the Merchant Venturers' School, Bristol, is now almost complete. The whole of the building is not at present supplied with the current, as it is the intention of the authorities to allow the students of the electrical engineering department to undertake each year the wiring of one or more rooms until the whole are completely supplied. Considerable additional comfort to the students is anticipated from the introduction of the electric light, more particularly in regard to the evening classes.

Cathedral Lighting.—In the course of an interview, the Clerk of the Works at St. Paul's Cathedral, London (Mr. C. J. Harding), stated that the electric light, which will doubtless ultimately be adopted for lighting the Cathedral, will be supplied by plant placed in the crypt of the Cathedral. Several of the Cathedral authorities are not enthusiastic concerning the introduction of electricity, except for the fact that gas has been found most destructive to the decorations.

Church Lighting.—The proposal to light St. Jude's Church, Southsea, by electricity has met with an adverse decision from the Southsea Vestry, who have postponed consideration of the matter for six months, "just to see how the new illuminant answers."

Clacton.—The Local Board have recently received a proposal with regard to lighting the town by electricity, which they have negatived, but would be willing to consent to a reasonable proposal for a local company to obtain a Provisional Order, on condition that provision is made for the Board ultimately purchasing the undertaking upon reasonable terms if they should so determine.

Cowpen.—The contract between the Lighting Company and the Local Board expires on February 12th, and public tenders are to be invited for lighting the district for a term of years.

Digitized by Google

DEWSBURY.—The guardians have received an intimation from the Local Government Board approving of the plans for the scheme of electric lighting proposed to be carried out at the workhouse, but the Board thought it desirable that the guardians should reconsider their decision in this matter, as it was probable that extensive alterations would be necessary in the infirmary buildings in the near future. After discussion it was proposed to notify the Local Government Board that the scheme of the guardians was a comparatively inexpensive one, and should therefore be proceeded with, and asking that the period for repayment of the loan proposed to be raised for the purpose be extended to thirty years. A proposal that tenders be invited for the necessary work, which is estimated to cost between £2,000 and £2,500, was adopted.

EDINBURGH.—The Lord Provosts' Committee of the Town Council have accepted an estimate for the removal of buildings at Denver Place, the site of the proposed central electric lighting station. Sketch plans, which have been prepared by the borough engineer, have been submitted and approved generally.

——— The Town Council held a further meeting on Tuesday to consider as to whether the Council's permission should be given to the transfer of the lease of the Edinburgh telephones by Messrs. Dick, Kerr and Co. to a local company. Mr. K. Anderson strongly disapproved of the proposed transfer, and contended that the chief object of the Council in granting the lease to Messrs. Dick, Kerr and Co. was that they should be responsible for the tramway undertaking. After a lengthy discussion, the proposals of the Lord Provost's Committee to draw up conditions under which the sub-lease is to be granted was approved.

FORGERY.—At Taunton Assizes, Henry Everard Hunt, electrical engineer, late manager of the Taunton Electric Light Works, pleaded guilty to forging two promissory notes for about £300. Everything was done to mitigate the penalty, but Mr. Justice Williams sentenced the prisoner to twelve months' hard labour.

FRAUD.—Robert Mann, employed as local manager at Ipswich by the National Telephone Company, was charged with having made false entries in his account books with intent to defraud, and, after a long hearing, was sentenced by Mr. Justice Cave, at the Ipswich Assizes, to eighteen months' hard labour.

GLASGOW.—Electrically-lighted private carriages, the property of two well-known Glasgow citizens, have recently created some interest. At a lecture a few weeks ago delivered by General Roberts, these carriages were used for the first time publicly, and showed somewhat conspicuously against the carriage of Lord Kelvin, who was a visitor on the occasion, and whose carriage was not lighted electrically. One of the owners of the carriages is Sir W. Renny Watson, who, besides being by profession a manufacturing engineer, is chairman of the Glasgow and South-Western Railway Company. The carriage is fitted with three small glow lamps, one of which is placed in the roof and the other two on the outside of the carriage, in lieu of the ordinary side lanterns. A Lithanode Company's battery is used, placed under the driver's seat. The driver has control of a small switch for turning the current off and on for the side lights. The owner of the second carriage is Mr. J. M. Thomson, who is also a mechanical engineer, a member of the Town Council and of the Corporation committee on gas and electric lighting, and an enthusiastic advocate of the electric light. Messrs. Anderson and Munro have carried out the electrical work.

GUILDFORD.—At their meeting last week the Town Council adhered to their intention of objecting to the application of the Holloway Electricity Supply Company (Limited) for powers to undertake the supply of electric current within the borough. In the report of the General Purposes Committee, discussed at the same meeting, it was pointed out that the Council may shortly take into serious consideration the question of themselves undertaking the lighting of the borough by electricity.

LARNE.—The Town Commissioners have received a communication from Mr. J. W. M'Ninch, solicitor to the Board, from the terms of which they have come to the conclusion that they cannot safely enter into a contract for the lighting of the town with Mr. Norris, the liquidator of Messrs. J. E. H. Gordon and Co. A proposal has, however, been made to Mr. Norris, which may prove a solution of the present difficulty.

LEEDS.—The Yorkshire House-to-House Electricity Company (Limited) have, in consequence of the increasing demand for current, decided upon extending the Company's works, and the necessary tenders are now being invited. It is proposed to instal two additional 400 I.H.P. engines, with other plant to correspond. Mr. R. Hammond is consulting engineer, and the architects are Messrs. Milnes and France, Bradford. Commencing on April 1st next, the Company have decided to make reductions in the price per unit as follows:—Up to 1,000 units, 7d. per unit; beyond 1,000 up to 1,500, 6¾d.; up to 2,000, 6½d.; up to 2,500, 6¼d.; beyond 2,500, 6d.; subject to discounts of from 5 to 20 per cent., and subject to further discounts for prompt payments. By the new price list, a consumer using above 2,500 units, and paying his account within one month, obtains his current at 4½d. per unit. The works in Whitehall-road, Leeds, will only have been in operation eleven months at the date of the reduction coming into force.

LEEDS.—The Leeds Photographic Society held their annual exhibition of lantern-slides in the Albert Hall, Leeds, last week, when about 250 slides were shown upon a 22ft. screen by means of an arc lamp in the lantern, and this method of lighting was pronounced a decided improvement upon anything previously attempted by the Society, who have from year to year adopted various methods of lighting, more or less successfully. It will be remembered that a fatal accident recently happened in using an oxygen bottle lantern, and doubtless audiences attending these shows will feel greater security when the electric light is adopted, as in the case at Leeds. The lamp used was designed by Mr. Borland, and fits on the ordinary tray of the lantern in a similar manner to the limelight burner. The exhibition was a success, the whole of the screen being fully illuminated, notwithstanding its large size.

LLANDRINDOD WELLS.—In reference to the proposed electric lighting of this district, the Local Board have received a proposal from a contracting firm to put down a temporary plant as an experiment, and they have discussed the proposal. The Board have again deferred the consideration of the matter.

LONDONDERRY.—Citizens who are interested in the veterinary inspection of cattle are urging the Londonderry Port and Harbour Commissioners to introduce at once the electric light, which has already been sanctioned by the Veterinary Department of Dublin Castle. It is feared that unless Londonderry promptly takes the matter in hand, breeders and shippers will transfer their business to Belfast, where veterinary inspection by electric light is permitted. A suggestion was made that it was desirable that the Port and Harbour Commissioners should approach the Corporation, with the object of inviting them to undertake the lighting of the quays by electricity.

——— The Electric Lighting Committee of the Corporation discussed on Tuesday the desirability of applying to the Local Government Board for an advance of a further sum of £5,000 in connection with the electric lighting scheme, which is to be extended, the extensions including a further 60 arc lamps beyond the 160 already in position. The electric light has to face severe opposition in Derry, but so far the estimated cost has been so nearly confirmed by actual practice that the opponents of the electric lighting scheme have made little headway. The Corporation's contribution to the local gas company's funds is £2,500 a year, and it is estimated that the working expenses of the electrical installation will only be about £1,400.

MANSION LIGHTING.—Her Grace the Duchess of Montrose was present at the recent inauguration of the electric light at Chatsworth, and, as a result, has decided to entirely rearrange the electric lighting at her London house in Belgrave-square. The work has been placed in the hands of Mr. B. Drake, of Messrs. Drake and Gorham.

MONTREAL.—In the summer of 1893 a meeting was called at Montreal of prominent members of the electrical profession, and it was decided to form an electric club. This club has now been duly inaugurated, and we have this week received a copy of the constitution and by-laws. The club consists of gentlemen actively engaged in various branches of electrical work, and third and fourth-year students at the McGill University, &c. Associates comprise managers of electrical firms and members of other branches of the engineering profession.

NEWPORT.—The Parliamentary Committee of the Corporation held an adjourned meeting on Tuesday afternoon last to consider the report on the electric lighting scheme, which was referred back to them by the Council, to enable them to make further inquiries into the tenders received, with particular reference to the tenders of Messrs. Crompton and Co. and Messrs. John Fowler and Co. Nothing was definitely decided, except that the committee are instructed to accept the invitation of Messrs. Crompton and Co. to visit the works just completed by them at Chelmsford, and also, if possible, one of their latest installations in London. It is anticipated that a definite recommendation will subsequently be adopted by the Committee, and placed before the Council for acceptance.

NORTHAMPTON.—An exhibition of domestic and other electrical appliances has been held in the Town Hall during this week. This was the first electrical exhibition of any kind held in the town, and attracted considerable attention. It was held in aid of the funds of two deserving Northampton charities. Mr. H. J. Dowsing (of Messrs. Crompton and Co.), and Mr. W. E. Heenan, Manager of the Northampton Electric Light Company, gave an attractive demonstration of cooking by electricity, and explained the uses of a variety of electrical appliances, motors, cooking stoves, &c. Short lectures were delivered at intervals by Mr. Dowsing, to the delight of large audiences. There is probably no

Digitized by Google

feature of such shows in which the public take a greater interest than in the application of electricity to domestic uses.

OSWESTRY.—The draft Provisional Order of the Oswestry Electric Lighting Company has been under the consideration of the local authorities, and certain objections and suggestions made by the Town Clerk have been forwarded to the Board of Trade for their consideration. The Town Council recommend—(1) That the Board should satisfy themselves as to the ability of the Company to carry out the works; (2) that all works of opening up and reinstating streets should be done by the Corporation and not by the Company, and at the expense of the Company, and that the latter should deposit £100 as a guarantee that the expenses incurred should be paid, and that there should be a like provision for the water mains; (3) that the cost of lighting the street lamps should not exceed 5 per cent. profit on the Company's capital; (4) that a strict audit of the Company's affairs should be provided as specified; (5) that the Corporation should be at liberty to take over the works at 30 and 35 years instead of 42 years; and (6) that additional streets should be lighted beside those in the original draft. In a discussion which arose at the last meeting of the Council, when the proposal came up for ratification, it was especially stated by all the members who spoke that opportunity should be given to the local company to proceed energetically with the work, and that no obstacle should be placed in their way by the local authorities.

PLYMOUTH.—In order to provide an alternate means of lighting the magazines and shell rooms of large vessels, in case the bulkhead electric light should break down from any cause, the Admiralty are carrying out experimental trials with various patterns of electric hand lamps. The Cambridge Gunnery School at Devonport are trying the Bristol lamp, the Pitkin lamp, and a portable lamp made by Mr. Marsh. A report is to be prepared and submitted to the Admiralty.

RADCLIFFE.—The Local Board has instructed Mr. F. F. Bennett, M.I.E.E., of Messrs. Bennett and Druce, Preston, to prepare a report and estimates, and to recommend a system of electric lighting for the district.

SHERBORNE (DORSET).—An interesting lecture was given on Monday last at Horsington by the Rev. J. D. C. Nickham, assisted by Mr. W. Goodland, of the Sherborne Electric Installation. A number of exhibits were shown, including high-tension apparatus, Bristol accumulators, experimental fuses, &c. Reference was made to the recent discovery of petroleum springs near Horsington, which are, we learn, to be energetically developed.

STIRLING.—The Caledonian Electric Supply Company, whose application for a Provisional Order for the lighting of Stirling meets with the opposition of the Town Council, have applied to the Board of Trade, asking that the consent of the Council should be dispensed with, on the plea "that the memorialists believe and aver that the Corporation has no *bonâ fide* intention of applying for an Order next year, with a view of working the same." The memorial points out that two similar applications have been refused by the Council in former years. Answers are to be lodged by the Town Council in due course against the memorial.

VENTNOR.—The Works Committee of the Local Board have requested the Town Clerk to obtain information regarding the introduction of the electric light into the district, and he is to prepare a report for the next meeting of the Works Committee.

WOKING.—As no tender other than that of the local electric lighting company was received for the public lighting, that Company's tender has been accepted.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The forty-third half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held yesterday (Thursday) at Winchester House, Old Broad-street, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. George Draper) read the notice calling the meeting, and the minutes of the previous meeting, which were confirmed by the present meeting and signed by the Chairman. The report of the Directors was taken as read.

The CHAIRMAN stated that the gross revenue for the half-year under review, to September 30th last, had amounted to £369,967, or an increase of £17,576. Analysing the receipts from various sources they found an increase of £28,123 in the message receipts. There was an increase in the traffic with most of the different places, the principal being in the traffic with the Cape, India, and beyond. The total ordinary expenses for the half-year to September 30th amounted to £98,106, or a decrease of £691. The general expenses in London had been £9,255, or an increase of £135, and the working expenses at stations had been £75,707, or an increase of £1,221. Several of the items under this head showed substantial decreases. The principal increase was in salaries and wages of their staff at stations, £2,439, there being an increase of thirty-two clerks compared with the corresponding period of last year. This, together with the operation of the scheme to provide regular promotion to deserving *employés*, which had been fully explained at previous meetings, accounted for the increase under this head. Comparing the other items in the revenue account, they found a reduction of £989 for special repairs to buildings at Alexandria, &c. The repairs being completed, this account was now closed. There was also a decrease of nearly £1,000 in the amount carried to maintenance ships' reserve fund. They had carried as much to this account as in the previous half-year, but the difference had been subscribed by other companies hiring this Company's ships from time to time. The expenses attending repairs and renewals of cables had amounted to £31,906, or a decrease of £5,730. They had received during the half-year over £20,000 for the hire of their ships for cable-repairing purposes. They had also been fortunate in not having to expend so much cable in effecting repairs, so that although they had had five ships more or

Digitized by Google

less busily employed during the half-year, the cost of maintaining communication had been less than for some years past. After providing the usual amount for interest on debentures and debenture stock they were able to pay the usual interim dividend for the half-year at the rate of 5 per cent. per annum, and to carry forward the substantial sum of £86,252, which was the largest amount they had ever carried forward. He thought they would be satisfied that economies had been effected, and that the whole concern had been very closely and carefully watched. They had applied a further sum of £35,505 from the reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable and other expenditure, so that their capital expenditure on account of cables, landlines, &c., practically remained at the same figure as it did eight years ago. The total amount applied from the reserve fund from time to time now amounted to £1,922,000. This was a very large sum to take from the reserve fund, but it was practically working for the benefit of the Company. They had duplicated and triplicated their cables without increasing their capital, and they had thus placed the Company in as strong a position as it was possible for it to enjoy. They still had a large reserve fund. He thought they would regard the statement which he had made as a very encouraging one, but it had not been arrived at without great attention and care on the part of the staff and those who managed the staff. The Directors had been very modest in their demands as regarded any increase of remuneration. On the death of the late Managing Director the management of the Company was to some extent reconstructed. The arrangements made had entailed on the Company an additional charge of over £300, a very small sum, although he thought that the efficiency of the Company had been maintained and strengthened in every way by what they had done. The Directors were now working for at least £1,000 less than they were entitled to by the Articles of Association, but they might hereafter ask the shareholders to approve of a larger sum for the Board. At the same time he hoped he would be in a position to justify their making such a request, because they would not ask for anything further unless they improved the position of the shareholders simultaneously. They would find on reference to paragraph 5 of the report that the cables connecting Lisbon and this Company's general system with the Islands of the Azores was laid and opened for traffic in August last. This Company had taken a large interest in that cable, but, as he had told them before, they had received a *quid pro quo* by getting an extension for ten years of the exclusive rights which they had possessed for many years at Lisbon. They would, probably, be able to add to the revenue of the Company by the Azores cable. The Eastern and South African Company had laid the cable from Zanzibar to Seychelles and Mauritius. That Company received for this work a subsidy of £28,000 a year. The Eastern Company were, however, practically holders of all the stock in the South African Company. He could not tell them much of the results of the working of this cable yet, but so far as it had gone it had not disappointed them. They had effected an important saving by a change they were making in the Levant. The Island of Zante had been subject of late years to violent volcanic eruptions. Fortunately, their station had so far always been saved, but if another outbreak occurred it might be interrupted, and thus cause serious inconvenience to the working of their system. They, therefore, decided to remove the work done at Zante to the island of Syra, where they also had an important station. They estimated that this would effect a saving of from £1,700 to £2,300 a year, and he thought they would have greater stability and security for their general system. The work which he had at the last two or three meetings informed them was in hand had now all been successfully carried out, and had added strength to their position, and had helped them to reach the sound and proud position occupied by them at the present time. Telegraphy, too, must go on. It would be their business to strengthen the system as much as they could, and wherever the British flag flies, wherever British commerce could show that it was to the benefit of this Company to be connected with it, they would make a great effort to make such connection. They had succeeded so far in connecting almost every part of the civilised world with their system. Their existence had been a comparatively short one, for they had not yet been 25 years in existence. They had, however, done an enormous work, the value of which was best tested by the opinion the investing public held of it. The £100 Four per Cent. Debentures issued by their Company were worth that day about £116 in the market. He had given them a very rosy description of the Company's position, but at the same time they had skeletons in their cupboard, as well as other people had. They had, for instance, the difficulties of the exchange, and the silver question very materially affected the remittances they received from abroad. They endeavoured to meet this by inducing the countries to allow an increase in the rate when they lost by exchange, but they could never do this to the full extent. They had to give a thoroughly efficient service, while at the same time they could not be too exacting upon commerce. As long, however, as the Directors could submit such a satisfactory account as that which related to the past half-year's working, he thought that the shareholders would agree that the Company was doing fairly well. He concluded by moving—

"*That the report and accounts of the Directors to September 30, 1893, submitted to this meeting, be and are hereby received and adopted.*"

The VICE-CHAIRMAN (the Marquis of Tweedale) seconded the motion.

Mr. BAINES said he thought that the shareholders ought to receive something to represent the large amount which had been expended on the property out of the reserve fund, and he thought that shares might be issued for the purpose. The shareholder would then be able to get the benefit of the improved position of the Company if he chose to sell. The property had increased in value, but the shareholders had nothing to represent it. He also inquired whether, in the event of war, the cables were in any way neutralised.

Mr. JOHN NEWTON said he considered that the addition to the directors' remuneration mentioned by the chairman was a very modest one, although if it had been proposed 20 years ago he would probably have opposed it. However, having had 20 years' experience of what the directors had accomplished for them he now desired to say that he entirely agreed with the increase. He referred to the sound investments forming their reserve fund, and contrasted them with what had been acquired by directors of certain other companies, of whom so much had been heard of late. He thought that the reserve fund and the market value of the shares constituted a substantial representation of their property, and this had arisen from the satisfactory dividends that had been paid. He was interested in some of the shares at the low prices of 7¼ to 8, at which they used to be quoted.

The CHAIRMAN, in reply, said that the legal adviser of the Company informed him that the suggestion made by Mr. Baines was illegal. Large dividends were desired generally by shareholders, but he would point out that they were working a system respecting which they had a good deal to learn yet. They could see how a railway was working and where it was undergoing depreciation, but they could not say so much yet with reference to submarine cables. It was, therefore, wise in the interests of the shareholders, and prudent on the part of the Directors, to increase the reserve fund, so that they might not be placed in the position, if they required to renew a cable, of not having the means to carry out the work. As Mr. Newton had intimated, the shares had about doubled in value; but the shareholders could not have their property doubled in value and the increase of dividend at the same time. They paid a steady dividend of 5 per cent., and at the end of their year they had hitherto given a bonus of 1½ per cent. He thought they would continue this, and he would be delighted if they could prudently increase the bonus. With reference to the question asked by Mr. Baines, he (the Chairman), many years ago, went and saw a gentleman of very high position at the Foreign Office. He asked that gentleman whether he would agree to sign a document, getting the nations of Europe to neutralise the cables in time of war. The reply he received was, "I will sign it to-morrow; but if a war occurred the naval or military officer who commands at the spot would break it." He only hoped, however, that they would not be destroyed, although there was the power to do so. He thought the cables would be used to a very great extent either in war or peace; but they were made for peace.

The resolution was then carried unanimously.

On the motion of the Marquis of Tweeddale, seconded by Mr. George Garden Nicol, Sir John Pender was unanimously re-elected to his seat at the board, as was also, subsequently, Mr. Charles W. Stronge, C.B., on the motion of the Chairman, seconded by Lord Sackville A. Cecil.

Mr. JAMES GIBB afterwards proposed, and Captain Goodsall seconded, the re-election of the retiring auditors, Messrs. Deloitte, Dever, Griffiths & Co., and Messrs. Walton, Jones & Co.

The CHAIRMAN remarked that their accounts were audited not only every six months, but, practically, continuously by the firms in question.

Mr. BAINES then proposed, and Mr. W. Griffith seconded, a vote of thanks to the Chairman, Directors, and Staff for their efficient administration of the Company's affairs.

The resolution was carried unanimously.

The CHAIRMAN, in acknowledging the vote, said that there was nothing pleased him more than to find that the shareholders appreciated the work done by the Directors, and he was glad to find their work recognised, especially by those shareholders who in former days used to hit very hard in their criticisms. They had a machine which was working harmoniously in all its parts.

(We shall publish a full report of this Meeting in our next issue.)

Direct United States Cable Company (Limited).

The thirty-third ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Tuesday, "to receive the report of the Directors and the accounts for the six months ended December 31st, 1893, and to transact other business of the Company." The chair was taken by Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. T. Finnis) having read the notice convening the meeting and the minutes of the previous ordinary general meeting, which were confirmed,

The CHAIRMAN said: Gentlemen, you have had the report in your hands for some days, and I presume you will take it as read, but before I ask you to adopt it, I will, as usual, go over some of the details of the last six months' working, so that you may probably have a better idea of what we have been doing than even the report gives you. The revenue for the half-year to December 31st last, after deducting out-payments amounted in round pounds to £41,052, and the working and other expenses, including income tax, to £19,060, leaving a balance of £21,992 as the net profit for the half-year, making, with £819 brought forward from the previous half-year, a total of £22,811, which has been appropriated as follows:—Interim dividend of 3s. 6d. per share for the quarter ended September 30th last, £10,624. 5s.; interim dividend of 3s. per share for the quarter ended December 31st last, £9,106. 10s.; balance carried forward, £3,080. 10s. 10d.; making a total in round figures, as above, of £22,811. The revenue, as compared with that of the corresponding period of 1892, shows a falling-off of £2,577, owing to the severe commercial depression which has prevailed, and to the interruption of several of the Atlantic cables. The expenses in London remain practically unaltered. They are, on the whole, within £72 of the same amount as in the corresponding period of 1892. The expenses at stations show as follows: Increases of £177 in wages, £66 in rent and taxes, £26 in travelling, and £52 in repairs, these increases being chiefly due to the working

Digitized by Google

of additional stations. On the other hand there are reductions of £54 in maintenance, £31 in petties, £64 in printing and stationery, and £123 in agencies, these disbursements on the whole showing an increase of £38 for the six months. In the remaining expenditure the only difference to note is an increase of £80 in income-tax, due to the higher rate of assessment. A comparison of the half-year's expenditure on the whole, but excluding the item of income-tax, shows the total to be within £2 of exactly the same amount as in 1892. It may, perhaps, be mentioned here, that, differing considerably from railway and many other companies, this Company is bound not only to keep the whole of its through system in full and continuous running order, but also to keep it all times fully and efficiently manned, whether business be brisk or slack. Consequently the ordinary working expenditure is not affected so largely as might be supposed by fluctuations in traffic one way or the other. As a matter of fact, however, the Company has carried considerably more traffic during the past six months than it did in the same period of 1892, although its share of the joint receipts has been less. The reserve fund, increased by the interest on the investments £3,979. 18s. 3d., now stands at £271,395. 10s. 10d. The investments, standing in the balance sheet at a cost of £234,152. 13s. 7d., are worth at present market values about £257,000, or 10 per cent. above cost. You will therefore see that the investments, as far as they are concerned, have been well made, and have stood the test of the bad times through which we have passed, and that they are to-day 10 per cent. better than when we invested in them. Before asking you to approve of the report, after having given you these details, I think it is also desirable to give you practically as much information as we ourselves possess, not only with regard to the present and the past, but also with reference to the future. I may mention that the December period, which is only the first half of our financial year, is always much more profitable than the period to June 30th. Notwithstanding this, and even with the reduced dividend, we are only able to carry forward to the poorer half-year, be it remembered, a balance of £3,080, or, allowing for the amount brought into the account from the previous half-year, a balance of only £2,261, and this without any provision whatever for the reserve fund. Now, you are aware that our shares are £20 shares, and the market price of them to-day is £11. I think it is right that I should tell you, looking to the coming year of Atlantic traffic, that every provision is being made for conducting the traffic in a thoroughly satisfactory way. Two new cables are going to be laid down. The Anglo-American Company are going to lay down one and the Commercial Company the other, so that, as far as the public service is concerned, it will, perhaps, be done more efficiently, if that be possible. I believe that the cable which is to be laid by the Anglo-American Company will probably be the best that has ever been laid in the Atlantic. It will be a very large carrier, and I hope that it will add to the "pool." The exchequer is the thing, after all, that we have to look to, because it is through that exchequer that I appear before you to-day in declaring our dividend. I may also mention that during part of the last year, out of the ten cables working in the Atlantic, several have been interrupted, and four are down at the present time, three of them being "pool" cables. If these cables had been working and earning and adding to the "pool," probably we should not have reason to reduce your dividend to-day by the ½ per cent. that it is diminished by; but I always think it is better to be wise, if we can, beforehand, and I thought, and my Board entirely agreed with me, that by reducing our dividend now, and carrying forward a larger sum, we should strengthen the value of your property more than if we had paid you a dividend "up to the hilt." We believe that the latter course would rather have lowered the value of your property instead of strengthening it, as we believe it will be now by the larger sum we carry forward, These three cables being out of working order have materially affected the earnings of the "pool," but, in view of the new cables that are about to be laid, I am hopeful that we may, perhaps, show a better result in the current year. I do not want to be too sanguine, and I do not like the look of things just now. We have not got through all our troubles commercially; and while we have held our own probably better than most other companies in existence in London during these hard times, still I do not like the continued depression. Although we may see some slight signs of improvement at the present time, still it will take a considerable time to get back into our old prosperous days. When I last addressed you I referred to the state of things in America. It was very bad then, and things have been very much worse since, but I think we see now a little more sunshine appearing, and I am hopeful that the traffic between America and this country may be benefited in consequence of that improvement. I have had a letter from one of the shareholders, and only one letter, but I think it is right that I should refer to it here. This gentleman complains very much about our reducing our dividend from 3½ per cent. to 3 per cent. He thinks that we ought to have done many things before we reduced our rate, but no one can eat his cake and have it too. If we have maintained, as I hope, the value of your property, you cannot have it in dividend as well, but this difference in dividend is not thrown away or wasted. You see where it is. This gentleman speaks of the miserable dividend we are paying, but I have gone into this matter, and I find that the bulk of the present shareholders possess their shares at something nearer £10 than £20, and consequently there has been no "miserable dividend" paid to our shareholders. During all this time we have paid upon the £20 shares a dividend averaging 4 per cent., and that upon £10 to £12, within which prices the great majority of shares have been acquired, gives from, say 8 per cent. to 6⅔ per cent., and that has been the return paid by us during the past 16½ years. The gentleman who has written this letter proposes to come to our next half-yearly meeting and take you all into his confidence, and get you to turn against the Directors for the great mistake, as he regards it, that they have made in reducing the rate of dividend to-day; but I would tell him that we who sit on this side of the table have to look ahead. I say that it was more prudent to carry this amount forward, and to pay the smaller amount of dividend, seeing that it is not a bad dividend on the cost of the shares. I may also go back and say a little more about the history of this Company. When the present Board joined it, the Company had been four years in existence, and no dividend was paid at all, and a debt of something like £100,000 was incurred. What have we done since we became your Directors? We have not only paid you for a large portion of the time 5 per cent. upon the £20 share, but we have passed through some hard times. The sixpenny tariff, for instance, cost us £25,000, the removal of our cable to Halifax cost £23,000, and we have had some heavy repairs. Remembering also the reserve fund that we have formed, and that we possess to-day, I think that our record on this side of the table is one that ought to be applauded rather than depreciated. At the same time we do not object to being pulled up if we are retrograding in any way, but I am quite sure that the step we have taken at the present time, seeing that the money is not wasted, is a step which the common sense of the body of the shareholders will approve. As you are carrying these figures away with you, I may also mention a few more, for I think it is worth while for you to know them. Since we took over the Company in 1877 we have paid in dividends £783,159; we have paid for cable repairs £165,000; the debentures and loans we have wiped out amount to £100,000; and the reserve fund amounts to £271,395. Those sums added together make a total of £1,319,554. This is a very good statement to make, I think, and one which I feel quite sure will be appreciated by the body of the shareholders. Before closing my remarks I may say a few words with respect to the position and prospects of cables in the Atlantic. I have already said that there are four cables down, and that there are six which are in operation. I believe that these six cables, working duplex, as they ought to do if they are in perfectly good order, are about equal to the work of the Atlantic at the present time. The putting down of the new cables is burdening capital with the amount of their cost, which will be nearly £1,000,000 for the two. At the same time the telegraphing public will benefit, although I do not myself think that a field which is over-supplied with the machinery that is necessary for conducting the business has a bright prospect of a large increase. Looking at the history of telegraphy, its progress for a time was something like 10 per cent. per annum, but during the past 20 years, with the changes we have seen in the tariffs, and in one thing and another, we have never yet got up to the £1,000,000 which we thought ought to have been attained many years ago. We are at a sort of standstill at the present time, and that standstill must continue as long as we have more cables in the Atlantic than are required for doing the work; but at the same time, it is almost as impossible to give up telegraphing across the Atlantic as it is to stop time from moving. Telegraphing has become a great necessity now, and we have touched a point in rates so low that the capital invested, in my opinion, looking at the number of cables that there are likely to be, will not meet with a very largely increased dividend. I shall be satisfied if we can maintain the position we hold at the present time. The time will come when we may require to lay another cable too. Our cable is getting to an age which must make us look to the laying of another. I think that, looking at the value of our stock and at the fact of our reserve fund amounting now to nearly £300,000, there is no cable in the Atlantic at the present time that holds a better position than ours; and if the time should come when the rates have to be lowered, I think that our system is worked in a way so economical that we shall always be able to take a leading part and obtain our share of the Atlantic traffic. I think I have now made nearly all the remarks I had to submit to you on the present occasion. As a rule I look to the bright side of the picture, and looking at the bright side of it to-day, so far as regards the work to be done in the Atlantic by the cable companies, I believe it will be well done, and done in such a way as will conduce to the benefit of the shareholders as well as to that of the telegraphing public. I now have to move the following resolution:—

"*That the report of the Directors, dated January 9, 1894, together with the statement of accounts to December 31, 1893, annexed thereto, be and the same are hereby received and adopted.*"

Mr. E. M. UNDERDOWN, Q.C., seconded the motion.

Mr. RUSSELL ENDEAN said that he had listened with much patience to the Chairman's statement and explanation why the dividend had diminished, but he would propose an amendment that the dividend on this occasion should be 3s. 6d. per share, as usual.

The SOLICITOR (Mr. Godlee) said that the shareholders could not increase the dividend recommended, according to the Articles of Association of the Company.

The CHAIRMAN: Perhaps you will give us your reason for wishing to increase the dividend.

Mr. ENDEAN said that the difference of giving a dividend of 3s. or 3s. 6d. was covered by about £1,500, and if there were ample funds to give the 6d. extra dividend, and still to carry over a balance of more than £1,500 to next half-year, there could be no particular reason why 3s. 6d. should not be paid this quarter, as usual.

Mr. UNDERDOWN: Article 95 says, "No larger dividend shall be declared than is recommended by the Directors; but the Company in general meeting may declare a smaller dividend."

The CHAIRMAN: Probably your opinion might be a guide to us next six months; but we who are sitting at this side of the table consider matters very carefully. We have shown you what the Board has done during the past 16½ years. We have worked faithfully and honestly for you, and we have built up a concern which is valuable. Surely we must be the best judges as to whether it is a wise proceeding to reduce or to increase the dividend at any particular time. We have not thrown away your money; you see where it is. The small amount that you refer to would be very small indeed in the pockets of the shareholders; but it is a largish portion for us to add to the reserve fund. There is another reason for what we have done. After all, this as an investment is a little uncertain. We cannot control cables laid in the Atlantic. It is not like a railway, and we must

Digitized by Google

look ahead. There has been a great deal of talk about our reserve funds. Our reserve funds, however, have been the making of these companies, and I am quite sure that you will find your property stronger through carrying this amount forward than even if you got your 3½ per cent.

Mr. ENDEAN said that if the dividend had been 3s. 6d., as usual, this time, no ill effect would possibly have been seen as regarded the market price of the shares, but in his opinion the giving of a 3s. dividend only, coupled with the statement just made by the Chairman relative to the prospects of Atlantic telegraphy, must operate to reduce the value of the shares, if they operated at all; and, therefore, he considered it most important that there should be no reduction in the dividend on the present occasion.

The CHAIRMAN: Does any other shareholder wish to ask any question? If not, I will put the resolution, but first let me say that there is no greater pleasure that a Board can have than to add to the dividend, and it gives them a considerable amount of thought when they reduce it. We have reduced it this time by a very small amount, but during the hard times we have passed through we have had on more than one occasion to draw something from our reserve fund in order to supplement the dividend. We have been particularly careful of the interests of the shareholders, and particularly anxious to give them as full a dividend as we considered ourselves justified in paying. The investments forming the reserve fund, to which I have referred, and which are stated in our report, are all good, and of better value than when we bought them; and you will also find that during all the hard times that we have passed through, this Company's shares stood the test of the market, while the shares of other companies went down "hand-over-hand." He then put the resolution, which was carried unanimously. Continuing, he said, I may add, gentlemen, that the present is only an interim dividend. I shall be delighted when we get to the end of this year if we can recoup what we have taken away from you this time. You may depend upon it that it will be a very great pleasure to us if we can do it.

Mr. JOHN NEWTON proposed a vote of thanks to the Chairman and Directors. No one else had thought proper to make any remark with respect to the reduction in the dividend, and for his own part he was glad that the Directors had taken the view they had, and had thus strengthened the value of the Company's property.

Mr. ENDEAN seconded the motion, which was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I thank you. I may say that we have had a good deal of experience in managing telegraph companies, and upon the whole I think that those which we have had to do with have been, in the main, very successful. It is a grand thing to have a good account at your bankers, and it adds immensely to the stability of a company. It encourages not only those who are managing the concern, but it is also very encouraging to shareholders to know that there is a reserve in case of any hitch taking place. We are in such a position that in the event of a hitch occurring we are prepared to meet it.

The proceedings then terminated.

St. James' and Pall Mall Electric Light Company, Limited.

The following is the report of the Directors of this Company for the year ended 31st December last, to be submitted to the shareholders at the meeting to be held at the Offices, Carnaby-street, Golden-square, London, W., on Tuesday, the 30th inst., at three o'clock:—

The Directors annual report for 1893, and the accounts accompanying the same, have been duly placed before the Board of Trade.

The judgment in the action brought against the Company by Dr. John Hopkinson in connection with the infringement of his three-wire patent was only delivered on January 14, 1893, the day of the issue of the last annual report. The Company, in resisting Dr. Hopkinson's claim, were acting in conjunction with the London Low Tension Supply Companies generally. The Directors, after fully considering the effect of this judgment in consultation with their experts, deemed it better to compromise with Dr. Hopkinson rather than run the risk involved in further litigation. They are happy to report that a compromise was effected on very favourable terms, under which the plaintiff waived his costs and granted a licence to the Company for the remaining term of the patent and any extension thereof. The cost of the licence and the proportion of law expenses attributable to this Company, amounting together to £4,446. 8s. 9d., is considerably less than the additional sum that would have been expended on the mains had the Hopkinson system not been adopted. This expenditure has therefore been carried to capital account. During the year the Company has also been involved in litigation with certain holders of founders' shares, who claimed a moiety of £2,000 forming the basis of the "Redemption Fund." This they successfully litigated, and one-half of the £2,000 has been divided amongst them. The other thousand pounds has been carried to the "Ordinary Shareholders Undivided Profit Account." The decision of the Court prohibits the Directors from following a policy which all four judges who heard the case approved, and which was directed to conserving the assets of the undertaking for the benefit of the shareholders generally. It is obvious that the ordinary shareholders should not be asked to build up a Redemption Fund in which it is possible that the founders might ultimately participate to the extent of 25 per cent. under clause 122 of the Articles of Association of the Company. An action brought by the Windham Club was settled upon terms satisfactory to the Company.

Having regard to the increasing demand for current, and for other reasons, it has been deemed necessary to arrange for an enlargement of the Carnaby-street Central Station, and in view of this the Company has purchased land on the north and south sides of that station. Plans for this extension are being got out. The Directors are considering the issue of debenture stock under the Company's borrowing powers to provide the necessary capital.

At the commencement of the year, the Company which possesses concurrent powers in the Parliamentary area allotted to this undertaking, started a system of competition which the Directors regret to report led to a reduction of price of supply with a consequent decrease of income. This reduction the Directors resisted as long as they could prudently do so, but it became clear in the spring of the year that unless they were prepared to lower the cost of supply they would lose the business that had been built up during the last few years. It is an encouraging feature, however, that the number of the Company's customers has largely increased. From this and other factors working in the Company's interest, the Directors believe they may safely hazard the opinion that the diminution of dividend is temporary only, and that in future years the income of the Company will justify a larger return to the shareholders.

The coal crisis which has affected so many classes of trade detrimentally has not affected this Company, for the reason that they had previously secured a contract, continuing until the end of March next. They are also pleased to rep rt that the cost of producing the current has not been increased, but is something below the figures of last year.

The shareholders will observe that the securities representing the "Capital Reserve Fund" have been altered. This was done to enable the Company to enjoy a larger rate of interest than they could under the original investment. It will also be noted that, although the "Redemption Fund" no longer exists, the securities representing it had not been sold. The amount is invested in Bank stock, which has depreciated, and the Directors, being of opinion that this depreciation is only temporary, do not feel it desirable to realise at existing quotations

The year has been one which has given the Directors much extra work and considerable anxiety, and they trust that the fruits of their efforts to protect and conserve the interests of the Company may show themselves in future years.

The net earnings of the Company during the past year have amounted to £10,552. 2s. 7d. Of this sum £3,500 was distributed in July last in payment of an interim dividend at the rate of 7 per cent. per annum for the half-year ending June 30th, on the preference shares. The balance £7,052. 2s. 7d., together with the undivided profit of £63. 16s. 2d. from last year's account, and, the £1,000 carried from the "Redemption Fund Account" to "Ordinary Shareholders Undivided Profit Account" leaves £8,115. 18s. 9d. now to be dealt with and the Directors propose to divide this amount as follows:—

	£	s.	d.
A dividend at the rate of 7 per cent. per annum on the Preference shares for the second half of the year	3,500	0	0
A dividend at the rate of 4½ per cent. per annum for the year on the Ordinary shares....................	4,495	10	0
Forward to "Ordinary Shareholders' Undivided Profit Account"................................	115	19	7
Carried forward to "Founders' Undivided Profit Account" per last year's report and accounts	4	9	2
	£8,115	18	9

The Directors consider that the amount set aside for depreciation in addition to the expenditure on renewals, repairs and maintenance is sufficient.

The Chairman, Mr. Eustace Balfour, and Mr. Latimer Clark, F.R.S., retire by rotation, and being eligible, offer themselves for re-election as Directors, and the Directors propose to nominate Mr. Bennett Fitch, M.I.C.E., for election as an additional Director. The Auditors, Messrs. Deloitte, Dever, Griffiths & Co., also retire, and, being eligible, offer themselves for re-election.

City and South London Railway Company.

The following report of the Directors of this Company will be submitted to the half-yearly ordinary general meeting, to be held at Winchester House, E.C., on Thursday next, February 1st, at 12 o'clock:—

The receipts from all sources for the past half-year have amounted to £22,821. 7s. 9d., and the cost of working has been £14,761. 11s. 3d., leaving a profit of £8,059. 16s. 6d. Inclusive of the balance brought forward from June 30th last, the net revenue account shows an aggregate total of £8,927. 10s. 7d. After making provision for the debenture and debenture stock interest, a balance remains available for dividend of £4,792. 8s. 10d. Out of this sum your Directors recommend the full dividend of 5 per cent. per annum be paid on the Preference shares, and that a dividend at the rate of § per cent. per annum be paid upon the Consolidated Ordinary stock, leaving a balance of £1,063. 13s. 10d. to be carried forward to the next account.

The following table shows the number of passengers, exclusive of season-ticket holders, carried since the opening of the railway in each half-year:—

Half-year.	Number of Passengers.	Receipts (including season tickets). £	s.	d.
Ended December 31, 1890 (11 days)......	165,000	1,568	3	9
" June 30, 1891	2,412,343	19,403	6	9
" December 31, 1891	2,749,055	19,798	16	6
" June 30, 1892	2,813,162	20,931	4	2
" December 31, 1892	3,117,602	22,002	17	5

The traffic for the past half-year was prejudicially affected by the long continuance of exceptionally fine weather, and by the closing of Kennington Oval for the purpose of relaying the turf, so that no football matches have been played there this season. These causes, added to the general depression of trade, have caused a slight diminution in the number of passengers carried, but notwithstanding this the general revenue receipts show a small increase over the corresponding period of last year, and the cost of working has been further reduced in spite of a considerable addition which has again been made to the local rates.

The locomotives, rolling stock, generating and other plant have been adequately maintained, and are in efficient working condition. The additional rolling stock referred to in the last report is in course of delivery. The new sidings at the Stockwell Station are now in use and prove a great convenience in working the traffic. The alterations at the King William-street Station are nearly completed. These will greatly enhance the comfort and convenience of passengers, and, at the same time, provide a ladies' waiting room, and a room for left luggage and parcels, which will be a source of revenue to the Company.

In the course of the half-year £32,200 of the terminable 5 per cent. mortgage debenture bonds have been paid off, and are being re-issued as 4 per cent. perpetual debenture stock.

The Bill promoted by this Company for the extension to Islington and other purposes received the Royal Assent on August 24th last. The Parliamentary expenses incurred in connection with this Act were largely increased by it having been carried over from one Session to another owing to the dissolution of Parliament, but having paid dividends in the meantime on the Ordinary stock, the Company is now relieved from the obligation to provide the Parliamentary deposit, whereby a very considerable saving will be effected.

The Directors retiring by rotation are Messrs. Sampson Hanbury and Spencer Barclay Heward, who are eligible for re-election. Mr. James Loriner is the retiring auditor and is eligible for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

DENISON AUTO-TELEGRAPH MACHINE SYNDICATE (LIMITED).—This Company was registered on January 18th, with a capital of £1,000, in 20 shares of £50 each, to purchase or otherwise acquire the letters patent of the Denison Auto-Telegraph Machine, for the United Kingdom, France, and Belgium, and for such other countries as the Company may think desirable, and to carry on the business of telegraphists, electrical engineers, manufacturers of and contractors for the sale, supply, letting on hire, erection, and maintenance of machinery for the purposes of utilising the said invention. The subscribers are:—James McLean, (2 shares); C. C. P. Ray, (2 shares); H. Kronheim, (1 share); C. Nolda, (1 share); L. R. Herzberg, (1 share); H. Baseley, (1 share); J. Korach, (1 share).

FOWLER, LANCASTER AND CO. (LIMITED).—This Company was registered on January 23rd, with a capital of £50,000 in £10 shares, to acquire by purchase or otherwise, and take over as going concerns, the businesses carried on by Fowler, Lancaster and Co. (Limited) and the Birmingham Telegraph Factory (Limited), Birmingham and elsewhere, to construct, manufacture, hire, let, license, purchase, sell, equip, maintain, work, use, and let on hire, electric light or power plant, or fittings, telegraph and telephone instruments and appliances, cables, wires, or other apparatus and things connected with or relating to the generation, accumulation, distribution and utilisation of electricity, and the transmission of messages, and generally to carry on the business of electrical engineers, contractors and manufacturers. The subscribers are:—T. G. McLauchlan, C. H. T. Bikker, Edward W. Lancaster, George E. Stembridge, C. O. P. Pemberton, George M. Fowler, W. Hand, with one share each. The first Directors are to be appointed by above-named subscribers.

FROGGATT'S ELECTRIC LIGHTING COMPANY (LIMITED).—This Company was registered on January 17th, with a capital of £3,000 divided into 1,500 Preference, or "A," and 1,500 Ordinary, or "B," shares of £1 each, to enter into and carry into effect an agreement already prepared and expressed to be made between Thomas Froggatt, of 55, Thomas-street, Kennington Park, London, S.E., of the one part, and the Company of the other part, for the acquisition by the latter of certain patents, patent rights, licences, concessions, and the like connected with or relating to electric lighting or advertising, or to the application of electricity, to develop, turn to account and deal with the said patents, and to carry on any business connected with electric lighting and engineering. The subscribers (with one share each) are:—L. Green, J. C. Hulbert, C. P. W. Pearce, Thomas Froggatt, jun., F. W. Hackforth-Jones, J. C. Genge, T. Froggatt. The first Directors are:—Adriano de Murrieta (Chairman) and Cristobal de Murrieta (nominated by the Preference shareholders), and Thomas Froggatt (nominated by the Ordinary shareholders).

CHARLES CHURCHILL AND CO. (LIMITED).—The annual return of this Company, made up to December 1, 1893, has been filed. The nominal capital is £6,000, divided into 140 Preference shares of £25 each and 50 Ordinary shares of £50 each. 103 Preference and 40 Ordinary shares have been taken up, of which 50 Preference and 40 Ordinary were issued as fully paid. Upon the remaining 53 Preference shares the full amount has been called, and £1,325 paid in respect thereof.

CRYSTAL PALACE DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to December 1, 1893, has been filed. Out of a nominal capital of £100,000 in £1 shares, 28,586 have been taken up, and 14,166 issued as fully paid. On the remainder £17,430 is said to have been paid; £3,264 has been received on 3,264 forfeited shares.

DISTRICT MESSENGER COMPANY OF PARIS (LIMITED).—The statutory return of this Company, made up to December 22nd, has been filed. The nominal capital is £200,000, divided into 112,000 Preference shares of £1, 80,000 Ordinary of £1, and 400 Founders' of £20 each; 67,875 Preference, 30,082 Ordinary, and 400 Founders' shares have been taken up, of which all the Founders', 20,000 Preference, and 20,000 Ordinary, were issued as fully paid. Upon the remaining 47,875 Preference and 10,082 Ordinary shares a call of 15s. per share has been made, resulting in the payment of £1,841. 5s., and leaving £41,626. 10s. as yet unpaid.

CITY NOTES, &c.

BALFOURS AND COMPANY (LIMITED).—The winding-up order was made against this Company in July last, when the accounts showed a deficiency of £3,682 to creditors, and to contributories of £20,867. This Company was associated with the promotion of the Alliance Aluminium Company, which is also in liquidation, and also of the "Postal Undertaking," for the automatic sale of postage stamps and post cards.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is hereby given that the coupons in this Company's Five per Cent. Debentures (1884 issue), due on the 31st inst., will be paid on and after that date, at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, London, E.C. Coupons must be left with the Bankers three clear days for examination.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended January 21st, were £947, as against £973 for the corresponding period of last year, being a decrease of £26. The total receipts for the half-year amount to £2,877, as against £2,978 for the corresponding period of 1893, a decrease of £91.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce that on Monday next, the 22nd inst., they will open a branch station at 449, Strand, London, W.C., opposite Charing Cross railway station, for the receipt and despatch of telegrams to India, China, Australasia, South America, Spain, Portugal, Greece, Turkey, and every part of the Submarine Telegraph System.

ELECTRICAL FINANCE.—Dr. Rosenthal, a representative of the firm of the Berlin Siemens and Halske, and Herr von Koenen, hitherto a leading official of the Seehandlung and an authority in financial matters, are, it is stated, about to establish a banking business in Berlin. This establishment, in which Messrs. Siemens and Halske are to be sleeping partners, will mainly direct its operations towards the financing of the electrical undertakings of the latter firm.

MANGANESE BRONZE AND BRASS COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 6s. per share, free of income-tax, payable on the 1st prox.

ROBEY AND CO. (LIMITED).—Letters of allotment and regret for the issue of £125,000 Four-and-Half per Cent. First Mortgage Debentures have been posted.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—It is announced that the second ordinary general meeting of this Company is to be held at Winchester House to-morrow (Saturday) at 12 o'clock, "when the Board hopes to be able to present accounts and declare a dividend."

SUBMARINE CABLES TRUST.—Notice is given that on and after 1st prox. the sum of £1. 5s. (balance of the coupon due October 15th last) will be paid by Messrs. Glyn, Mills, and Co., Lombard-street, E.C. Coupons should be left with the bankers for four clear days.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—Coupon No. 7 of the Five per Cent. First Mortgage Debentures of this Company, due for payment on January 31st, will be paid from that date at the Consolidated Bank (Limited), Threadneedle-street, or at the Banking House of Messrs. Westindorp and Co., Amsterdam.

VICTORIA (BRITISH COLUMBIA) ELECTRIC RAILWAY AND LIGHTING COMPANY (LIMITED).—Messrs. Sperling and Co., of 8, Austinfriars, E.C., have this week issued a prospectus inviting subscriptions for £100,000 Five per Cent. Debentures of £40 each in the above Company, at the rate of £98. 15s. per cent. The Debentures are redeemable in 1932 by the application of a sinking fund and annual drawings. The Company (the prospectus states) has for fifty years the sole right to work and organise electric cars, &c., in the city of Victoria, British Columbia.

WATERLOO AND CITY RAILWAY COMPANY (LIMITED).—A meeting of the proprietors of the London and South-Western Railway Company is announced to take place at the offices at Waterloo Station, London, on the 8th prox., at 12 o'clock, at which it will be proposed that an agreement be entered into between the London and South-Western Company and the Waterloo and City Railway Company in respect of the working, maintenance, and management of the railway authorised by the Waterloo and City Railway Act, 1893, and for the supplying, by the London and South-Western Company, of electrical energy, plant, and machinery, and for the guaranteeing by the company of dividends and interest upon the share and loan or borrowed capital of the Waterloo and City Railway Company's stock. Should this proposal meet, as it doubtless will, with the support of the proprietors, the Waterloo Company will have little difficulty in obtaining all necessary capital for their undertaking, as the stock of the London and South-Western Railway Company is considered a gilt-edged security, and any undertaking fostered by its Directorate is assured of success.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 820.—Vol. XXXII. FRIDAY, FEBRUARY 2, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

With such good material to start upon as that which was given in the *Pall Mall Gazette* in October last, the announcement on November 8th of the arrest of Harness, and the charge of conspiracy to defraud, seemed to betoken the end of the electropathic belt quackery. But after the first day or two of the long trial, it was evident that the case was a very poor one, and many of the witnesses did as much harm as good to the prosecution. Sufficient time and money have now been spent by private individuals to show that when these private individuals either prosecute or defend, the laws of this country or the procedure of its courts of justice are incompetent to deal with such practices as those which have proved so lucrative to the Medical Battery Company. It has been found impossible, owing to these causes, to utilise certain evidence which has been selected and prepared in a manner incomparably superior to that of this abortive prosecution. There is a general impression that there is an official of the Home Department, called the Public Prosecutor, and it has been hinted that he derives great comfort from the habitual use of an electropathic belt. The former, and consequently the latter, supposition is without foundation. Circumstances in 1872 led to the appointment in 1879, by special Act of Parliament, of such an official at a salary of £2,000 per annum, with six assistants. But in 1884 this appointment, so far as it related to the salary, and a few other details, was revoked, and it was ordered that the duties should be performed by the Solicitor to the Treasury. What are now known as Treasury prosecutions are chiefly of a purely financial character, and it is possible that the department shirks, while Harness pretends to court, a scientific investigation. We have little sympathy with his victims, for they throw away their money in the face of the unanimous opinion of all medical men of repute. The graver cases of extortion and of blackmail are to be distinguished from these, and here the Treasury need be less concerned with scientific details; the chief difficulty would be to induce witnesses to make their follies public. But perhaps we have, after all, heard the end of the business.

Notwithstanding that the "Report of the Action of the Traction Committee" was on the agenda paper for the meeting of the Electrical Trades Section of the London Chamber of Commerce on the 23rd ult., the attendance was so small that the meeting was adjourned till last Monday. The adjourned meeting was very thinly attended, and it might have been imagined that such confidence is placed in the ability of the Traction Committee that no one but a few telephone men cared to come to hear their report. The members of this Committee were, however, well enough aware that no report was to be issued, and those who came expecting to hear it had to content themselves with a statement from the Chairman that one of the privileges of the Chamber is that members may form special-purpose committees, even for objects diametrically opposed to the interests of other members of the same section, and may subscribe and spend their own money on such special purposes, and that the Traction Committee had taken this course. We are glad to hear that the Committee is busily engaged on the discussion of the proposed regulations from the practical and commercial point of view, and that a Committee of the whole Council of the Institution of Electrical Engineers is giving attention to them as well.

Although not making much noise, the Committee is not resting on its oars: far from it. The Board of Trade draft regulations, which we published in our issue of November 24th, have been submitted to exhaustive examination, and on Wednesday a lengthy conference, between Sir Courtenay Boyle, Sir Thomas Blomefield, and Major Cardew, and the members of the Committee, was held at Whitehall Gardens, at which the amendments suggested by the Committee were brought to the notice of the Board of Trade as a preliminary to more formal action. The sentiments expressed on either side were brimful of peace and goodwill, and the Chairman, who had evidently scarcely anticipated escaping with a whole skin, congratulated himself and the meeting upon the mild tone which had prevailed. When, however, we state that the obnoxious Regulation 14, which, in face of the letter and of the spirit of the Report of the Joint-Committee, places electric traction under the heel of the telephone interest, was passed over as too important and too delicate a matter to be discussed at such a friendly and informal round-table conference, all this amicability, following hard upon so much pugnacity elsewhere, gives no cause for bewilderment. One may wrangle over details; but one only fights over principles, such as those involved in Regulation 14.

At the present stage we do not think any useful purpose would be served by the publication in full of the suggested emendations of the Traction Committee, a large proportion of

Digitized by Google

which merely relate to matters of drafting, verbiage, and definition, and which will in all probability before long be deprived of their *raison d'être* by the issue of verbally amended draft regulations. But it may not be premature to state that amongst the more important suggestions of the Committee was the deletion of the last paragraph in Regulation 5, in which it is laid down that where an earth connection at the power house is within 6ft. of any pipe, and permission cannot be obtained to connect on to it, a non-conducting screen must be provided. It was intimated, however, that the Board of Trade considered this a very valuable provision, and its omission could not be entertained, although amendments were invited. Sub-section 1 of Regulation 6 lays down that the current passing from the earth connections to the generator is not at any time to exceed 10 amperes ; it was urged that this inextensible maximum might well be altered to "a certain percentage of the total output ;" but here again no great hope was held out of an alteration in the principle of a definite maximum earth current for all lines from one car upwards.

Regulation 9, providing for the breaking up of the line into half-mile insulated lengths, was thought to place "a very serious restriction upon electric traction," and Regulations 10 and 11, fixing the maximum leakage current at $\frac{1}{100}$th of an ampere per mile of tramway, and the minimum insulation resistance of "all lines, insulated returns, feeders, or other conductors laid below the surface of the ground" at 10 megohm-miles, were considered impossible of application to conduit systems. With regard to the last two regulations, the Committee was informed that these had been intentionally drafted stringently, with a view, we suppose, to determining the traction man's limit of elasticity. Objection was also raised to the proviso that the separate lengths of metal conduits shall be jointed, so as to secure metallic continuity throughout, but a reminder of the recent Bournemouth accident, due, we understand, to a neglect of this very precaution, silenced the objectors. The conferees then separated—to fight again another day.

A PROMINENT article in the *Pall Mall Gazette* of Tuesday last calls attention to the lax way in which ships are commonly wired for electric lighting, the absence of any Board of Trade regulations, and the non-enforcement of the "amiable suggestions" made by Lloyds. A slightly alarmist tone is adopted throughout the article, which is well calculated to attract attention. Seeing that there are staffs of surveyors in connection with marine insurance companies, and that the suggestions already issued by Lloyds' Committee need only to be slightly amended and transformed into positive and thoroughly enforced regulations, there does not at first sight seem any reason for appealing for help, as the Englishman in a difficulty is always ready to do, to the already much over-worked Board of Trade. But the wiring is bad enough even on some of the large liners, and the companies who own them "insure themselves." As life is concerned as well as property, and in a much more serious way than in house lighting, the Board of Trade, who already possess a large staff of marine surveyors, might have this duty added ; but there is no sense in having the work of inspection done twice over. The *Pall Mall Gazette* makes the good suggestion that "at least one engineer and one deck officer of every ship's crew should of necessity be certified as possessing theoretical and practical knowledge of electricity and the dangers involved in its unprotected use." Whether deck officers should go through a text-book and a course of amateur joint-making is perhaps doubtful, but one of the numerous documents which has to be signed before a ship is cleared might be a certificate of sound wiring and good insulation.

AT the annual meeting of the St. James' and Pall Mall Electric Lighting Company, held last Tuesday, the Chairman, while announcing very satisfactory progress, expressed his regret at sundry conflicting and damaging tendencies. Now, it is curious to notice that these tendencies, which the Chairman called upon the shareholders to deplore, are counted virtues among plain men. Firstly, the consumer had cultivated thrift ; and becoming more economical of his light, had reduced his "little bill" something like 25 per cent. As a set off against this, however, an increase of 25 per cent. in the number of lamps wired was announced. Secondly, the consumer had evidently been inquiring into the relation between "price per unit" and "cost of production," and had made up his mind that the supply company could well afford to reduce the former quantity. And he had very successfully enforced his claim, with the result of still another reduction in the bill. Lastly, Nature had been kindly to the consumer, and her smiles meant woeful loss to the Company; for the past winter had been one notably destitute of fogs, and such fogs as had occurred had selected Sunday for their appearance, so that the lucky consumer had been taking sunshine gratis, instead of electric light at 6d. per unit. But, to the Company, all these things meant a reduced revenue ; and the shareholders viewed them in the light of a lessened dividend.

IN a series of articles in the *Electrical World*, of New York, Mr. R. A. FESSENDEN describes a method which he has devised for preventing the escape of heat from any electrically-heated object. There does not appear to be very much novelty about the actual method proposed by Mr. FESSENDEN, and the principles upon which it is based have long been known ; but some interest attaches to the series of experiments which Mr. FESSENDEN has been making. The method consists in intercepting the heat, not by means of a badly conducting jacket, as is usually done, but by means of a series of highly-reflecting and badly-radiating surfaces. By this means the heat which is radiated from the hot body is largely intercepted and returned to that body by the first or innermost reflecting shell ; and the remnant which escapes the influence of the inner baffler is caught by an outer one, and, in like manner, is partially reflected back. In the experiments carried out by Mr. FESSENDEN it was shown that with a couple of polished tin boxes, arranged in the form of a nest, with the hot body in the very centre, and with but a quarter of an inch between the outer and inner boxes, radiation was checked to an extent which could only be equalled by a thickness of one and a-quarter inches of asbestos.

Digitized by Google

It is more than probable that these results would have shown even more in favour of the reflecting jacket had the air been largely exhausted from the space between the two boxes. The arrangement would then have resembled Prof. Dewar's vacuum jacket, with a mercury mirror deposited on the surface of the confining vessel. Instead of exhausting the space, Mr. Fessenden might have provided that the circulation of the air should be prevented; for air, even at atmospheric pressure, is a very good non-conductor of heat if convection currents within it are prevented. Considered as a practical method of retaining heat within a heated body, such as an electric oven or furnace, we are, however, afraid that some difficulty might be met with in keeping the nest of polished surfaces in a continual state of efficient brightness; while the necessity for perfect heat insulation between the successive jackets would render it a by no means easy matter to provide a door for communicating with the interior. Still, in some classes of work it might be found not only more efficient, but also more convenient, to employ these anti-radiators in place of, or even in conjunction with, the non-conducting lagging which is ordinarily used.

The magnetic permeability of oxygen in the gaseous state has long been shown to be greater than that of air in a corresponding condition of pressure and temperature; and the very high permeability of the former substance in the liquid state has been demonstrated by Prof. Dewar. But considerable discrepancies occur between the various determinations of the change of permeability of gaseous oxygen under changing conditions of pressure, temperature, and magnetic induction. An account of some recent researches on this subject by Hennig will be found in another column, together with an instructive pair of tables, the first of which gives the results of Hennig's own researches, and the second compares these with the standard figures obtained by other investigators. The probable causes of error, at least in so far as the method of Töpler which was used by Hennig, is concerned, would seem to consis in the difficulties of determining the thermodynamic conditions of the two gases in the two limbs of the V-tube, and in the irregularities of distribution of the magnetic induction. This last-named source of disturbance would to a certain extent be assisted, especially in strong fields, by the very difference between the permeabilities of the two gases in the two limbs; although it is possible that this cause of disturbance might be too small to affect the measured results. It does not appear that the method adopted by Hennig to determine irregularities in the induction distribution could eliminate the error of which we have just been speaking. It is noteworthy, however, that the results now obtained by Hennig are more nearly equal to the mean of all the determinations than the results obtained by the same investigator in conjunction with Töpler, in 1882.

Honours.—The Grand Cross of the Red Eagle has been conferred upon Dr. H. von Stephan, the German Imperial Minister of Posts and Telegraphs.

Steel Barrels and Electric Welding.—New machinery for the production of steel barrels is, says *Industries and Iron*, being put down at Barrow. The steel sheets which are used will be shaped by means of hydraulic presses when the metal is hot, and the half-barrels will be welded together by means of electricity.

The Theory of Heat.—Messrs. Macmillan and Co. will shortly publish "The Theory of Heat," by Prof. Thomas Preston of Dublin. The subject has been treated in a comprehensive manner, and in such a way as to interest the general reader as well as the student.

Aluminium.—The *Engineering and Mining Journal* of New York states that the Cowles Electric Smelting and Aluminium Company and the Pittsburg Reduction Company have not consolidated, as announced, nor does the Cowles Company expect to move its plant to Niagara Falls.

Personal.—Mr. W. B. Esson has severed his connection with the Gülcher Electric Light and Power Company, and has joined Messrs. Johnson and Phillips at their Charlton Works, where he will act as manager of the electric light, transmission of power, and electro-chemical departments.

Fatal Accident at Prescot.—According to the *Globe* a boy was killed by an electric shock at Prescot, near St. Helen's, last Wednesday night. The deceased, while assisting in repairing wires in a cellar of some business premises, accidentally got in contact with an exposed wire. He fell to the ground, being instantly killed. One of his hands was slightly burned.

Newport.—The sub-committee of the Town Council, who are entrusted with the conduct of the electric lighting of the borough, on Friday last visited Chelmsford for the purpose of inspecting the installation which Messrs. Crompton have provided in that borough. They also inspected another installation which the same firm have provided in the metropolitan area.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	October 15th, 1893
Bissao-Bolama	November 24th "
Cayenne-Vizeu	November 25th "
Garachico-Santa Cruz de Palma	December 27th "
Constantinople-Odessa	January 31st, 1894
Saigon-Thuan-An	February 1st "

The American Fire Losses of 1893.—During the year just ended the loss by fire in the United States in property value was almost $150,000,000, a greater loss than has been recorded in any one year, except that in which Chicago was burned, and that in which the best part of Boston was blotted out. Boston lost more last year than any other city, the estimate being $5,300,000.

Extension of Suburban Mains.—The Metropolitan Electric Supply Company have given notice to the London County Council of their intention to lay mains in Elgin-avenue and road, Carlton-road and hill, part of Edgware-road, Portsdown-road, Abercorn-place, Hamilton-terrace, Upper Hamilton-terrace, Abbey-road, place, and gardens, Violet-hill, Nugent-terrace, Alma-square, Hill-road, Garden-road, Grove End-road, Loudoun-road, Elm Tree-road, Circus-road, Hall-road, Melina-place, and Stranraer-place.

A Sidelight on Municipal Electrical Finance.—Some questions were put to the Chairman of the Huddersfield Gas Committee, at a recent meeting of the Council, as to the price charged for coke. From these it would seem that the Committee are disposing of coke to the Electric Lighting Committee for 6s. per ton, while other customers are charged 8s. 4d. Alderman Stocks explained that the Electric Lighting Department contracted for a supply of coke all the year round, while the other business was of a casual nature.

High-Pressure Alternate-Current Transmission at Chambéry.—A continuous current plant, which is at present at work at Chambéry (Savoy), is to be replaced by May next by a 5,000 volt alternate-current plant supplied by the Creusot Works. The generating plant will be some 12 miles from Chambéry and close to Chapareilan on the Cernou, where a 2,000ft. 2,000 H.P. fall is available. The plant will consist of 7-120 kilowatt turbine-driven alternators. The pressure will be reduced from 5,000 to 110 volts at one step, 10 kilowatt transformers being used.

Digitized by Google

Brighton.—Mr. Arthur Wright, manager of the Corporation's Electric Lighting Works, has reported that the result of the past year's working of the sliding scale has been that the average price charged for electricity is 6·1d., against the old price of 7d., which exactly corresponds to the 13 per cent. reduction anticipated by Mr. Wright in January last. The revenue for the year is, in consequence, £1,007 less than it would have been if no reduction had taken place. 150 consumers out of the 320 that were connected on June 30, 1893, have benefited by the reduction.

Polyphase Currents in 1893.—The following list of polyphase current plants actually at work is from *L'Industrie Electrique*:—*France.*—(1) St. Victor-sur-Loir, near St. Étienne, 3 200 kilowatt machines; (2) Port Lignon, 1 200 kilowatt machine; (3) Florensac (Hérault), 1 200 kilowatt machine. All these machines are of the Lauffen-Heilbronn type, and were laid down by MM. Guitton et Bertolus, of St. Étienne. *Germany.*—Four three-phase plants: Lauffen, Bockenheim, Erding, Wangen. *Austria.*—(1) Pergine, three phase; (2) Budapest, two-phase. *United States.*—Reclands (Cal.) three-phase.

The Niagara Scheme.—The "real estate men" of Buffalo are, it is said, considering plans for celebrating on a "royal scale the inauguration of the use of the Niagara Falls electric power in Buffalo." The plan most favored is to issue letters of invitation to President Cleveland and his Cabinet, Senators and Congressmen, Governors of States, and other high officials, all the eminent electricians of the world, and representatives of the press from everywhere. The wire conveying the current is to be connected with one of the large manufacturing plants near the city line and the machinery set in motion by the touching of a button.

The Hermite Process.—The committee appointed by the Counseil Central d'Hygiene to visit Havre and inquire into the results obtained in the lengthy experiments with the Hermite process of purification by electricity, which have beer made in the St. François district, have recently published a report which, says *Industries and Iron*, is unfavourable to the process. The committee state that the result of their investigations into the process, as applied under the conditions prescribed by M. Hermite himself, gives them the right to say that the process does not bring about a sufficiently rapid sterilisation of sewage, and consequently does not constitute a sufficient guarantee for prompt disinfection, but as it shares with certain chemical products the property of deodorisation it may, from that special point of view, and that only, have some hygienic value.

The Late Capt. Halpin.—Mr. F. C. Webb sends us the following account of an episode in the life of the late Capt. Halpin, whose loss we had to deplore last week, which is characteristic both of his courage and great physical strength:—

"As every seaman knows, the mainstay of any full rigged ship lies at a very acute angle with the horizon; and, consequently, to attempt to slide down it, or climb up it, is dangerous, as if the legs are let go from the stay and the seaman has not strength to regain his legs round the rope, he can only hang (or come down hand over hand) until exhausted and then must drop. So well was this danger known in the old line of battle-ships (and I had this from Capt. Frederick Bullock, R.N.) that the moment a man was seen on the mainstay with his legs gone from the rope then every man rushed to the hammock nettings to snatch the hammocks out and pile them up on deck to break his fall. Well, once a man was in this dangerous position on board the "Great Eastern," only instead of being over the *deck* he was over one of the engine-room skylights. He was in extreme peril when Capt. Halpin (then chief officer) went up the stay and rescued the man."

Acoustic Synchronizer for Alternators.—An acoustic synchronizer was shown by the General Electric Company at the Chicago Exhibition, and attracted much attention. It consists merely of a cylindrical iron case with an aperture in the side, each end being closed by a flexible diaphragm, each of which has opposite its centre the pole of an electromagnet. In using this device one of the magnets is connected in circuit through a transformer with each of the machines to be run in synchronism. The current is then turned into the magnet coils, and the diaphragms emit a loud clear note. As the machines approach synchronism, the notes from the diaphragms approach closer in period and begin that loud, periodic sound, known in acoustics as beats. As the two machines more nearly approach synchronous speed, the beats grow slower and slower, until finally, the diaphragms fall into unison and each gives out the same low, clear note. At this moment, which is sharply marked, the switch connecting the two machines is thrown in. So sensitive and distinct is the indication of approach of synchronism, that it is possible to throw two machines together with hardly a quiver upon the ammeter.

The Provincial Central Stations of France.—Our esteemed contemporary *L'Industrie Electrique* published in its issue of January 25th a list of the provincial electric lighting central stations at present at work in progress and projected in France; the list has been corrected up to December 31, 1893, and is accompanied by a map showing the location and nature of the different stations. There are, it seems, 301 central stations actually in operation in France outside Paris, 248, or 83 per cent., being on the continuous-current system, 47 on the alternate-current system, and 6 having the two combined. The oldest provincial station in France is that at Bellegarde-sur-Valserine (Ain), which came into operation in February, 1884; the first alternate-current station was that established at Tours in January, 1886. As will be seen by the list below, the total horse-power of the French provincial stations in operation, in progress and projected is equivalent to a capacity of about 750,000 8-c.p. lamps, that of our own provincial stations *actually at work* being 425,000 8-c.p. lamps. It may be observed that our Paris contemporary's list includes central stations (?) of 3, 5 and 8 H.P. capacity, and the majority are less than 100 H.P.:—

Motive power.	Stations.	H.P.
Hydraulic	136	9,259
Hydraulic and steam......	36	6,000
Steam	113	21,820
Producer gas	3	140
Town gas	13	1,015
	301	38,234

Perfect and Imperfect Combustion of Carbon.—In a Paper on the "Combustion of Carbon in Air," by R. Ernst, the author states that the oomposition of the products of combustion depends almost exclusiveiy on the temperature. The formation of carbonic anhydride begins at about 400deg., and at this temperature there is already a small quantity of carbonic oxide produced. The maximum production of carbonic anhydride occurs at about 700deg., and amounts to some 20 per cent. of the products, including the nitrogen of the air used; up to this temperature the formation of carbonic oxide is but small, hardly exceeding 3 per cent.; the oxygen, however, is entirely used. At higher temperatures, the carbonic anhydride rapidly disappears, giving place to carbonic oxide, until at 995deg. this gas amounts to 34 per cent., the remainder being atmospheric nitrogen. There was no further change in the composition of the products up to the highest temperature—1,092deg.—at which the author experimented. The production of carbonic oxide could not be induced at a lower temperature by altering the other experimental conditions. It is concluded that carbonic oxide is the only oxidation product of carbon at 1,000deg., and that producer gas should be prepared at this temperature. By substituting carbonic anhydride for air it was proved that this gas is never entirely reduced to carbonic oxide by the hot fuel, so that, where the production of carbonic oxide is preceded by that of carbonic anhydride, some of the gas must appear among the products of combustion; it may be concluded, therefore, that the carbon burns directly to carbonic oxide. In the rational furnace, where a high temperature is required, the air supply directly to the fuel must be only sufficient to burn it to carbonic oxide, which must subsequently be burnt by admission of fresh air. The temperature must be maintained at 995deg. and upwards. The observation that coke burns without flame at moderate temperatures, but with flame at higher temperatures, is, the *Journal* of the Chemical Society remarks, now explicable.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 289.*)

THE STEAM ENGINE.

Fuels.

Definitions. — Steam engine plant is a combination of thermal and mechanical parts having for its purpose the production of mechanical motive power from the energy known as *heat*, through the agency of steam. It belongs, therefore, to the class known as *heat engines;* and comprises the following parts: (1) the apparatus for the generation of steam by the heat of the energy source, with its accessory parts; (2) the engine, in which the energy of the steam is converted into mechanical motion, with its accessory parts; and (3) the mechanical parts by which the motion is transferred and adapted to the work. In the majority of cases heat engines, and steam engines in particular, derive their heat from the combustion of fuel; though in rare instances the direct heat of the sun's rays is utilised. The term *fuel* is applied to an extensive class of substances which have the property of developing light and heat by their chemical combination with the oxygen of the air, the rate at which the heat is generated being sufficient to maintain the process of combination without external heating. It is generally necessary to raise a fuel to a high temperature before this process can be started. *Combustion* is the name given to the process by which any substance maintains itself in a continuous state of entering into combination with the oxygen of the air, by virtue of the heat which is generated during the process. The term *products of combustion* is given to the chemical compounds which result from the combustion of fuel. These usually comprise gaseous products, smoke and ash.

Classification of Fuels.—The character of a fuel depends upon: (1) the ultimate constituents of the fuel, *i.e.*, the chemical elements; (2) the proportion by weight of these elements; and (3) the character of the groups of compounds into which these elements are arranged. Fuels are, for the most part, the products of protoplasmic activity, either animal or vegetable, though in some instances they are purely inorganic. They generally consist of one or more of the following elements: namely, hydrogen, carbon, sulphur, oxygen, nitrogen and earthy matter. Of these, one or more of the first three are essential to the conditions of the compound being combustible, and the remaining constituents are prejudicial. The useful fuel-elements, hydrogen, carbon and sulphur, are not equally valuable even in the elementary state, so that the value of the fuel depends upon the proportion of these elements to one another and to the whole mass. The elements in a fuel do not as a rule occur in the elementary state in the fuel, but are combined in various groups. The hydrogen, for example, may be combined, wholly or in part, with oxygen, forming water, or with carbon, forming bituminous and gas-producing matter, or with nitrogen, forming volatile ammoniacal compounds. In the first instance it would be very prejudicial to the value of the fuel; in the second, it would be highly useful; in the third, it would be only slightly prejudicial. As with the hydrogen, so with the other constituents; the actual value of each and all is determined by the proportion of each, and by the associations with the remainder which it forms. Hence the importance of a knowledge of the quantitative analysis of the fuel, in estimating its thermal value. Fuels may be divided into three classes—solid, liquid and gaseous; and the principal fuels in each class are as follows:—

Solid fuels.

Coal.	Wood.	Peat.
Coke.	Charcoal.	Dried vegetable matter.
Town refuse.	Straw.	Dried animal matter.

Liquid fuels.

Crude petroleum.	Petroleum oils.	Shale oil.
Vegetable oils.	Animal oils.	Alcohols and ethers.

Gaseous fuels.

Coal gas.	Water gas.	Dowson water gas.
Oil gas.	Producer gas.	Spirit vapour.
Natural gas.		

The special features of liquid and gaseous fuels are discussed later, as these are not frequently used in raising steam. Solid fuels and general considerations only will be dealt with at present.

Combustion of Elementary Fuels.—The elementary fuels are hydrogen, carbon and sulphur. Hydrogen enters directly into combination with the oxygen of air, by combustion, in only one proportion, namely, in the proportion of one part by weight of hydrogen to eight parts by weight of oxygen. Nine parts by weight of water are produced. Carbon enters directly into combination with the oxygen of air, by combustion, in two proportions. In the first, or *incomplete* combustion, one part by weight of carbon combines with 1·33 parts by weight of oxygen, forming 2·33 parts by weight of carbon monoxide. In the second, or *complete* combustion, one part by weight of carbon combines with 2·67 parts by weight of oxygen, forming 3·67 parts by weight of carbon dioxide. The first stage is produced by combustion in a limited and insufficient supply of air; the second, when combustion occurs in an abundant stream of air. The product of the first combustion is a poisonous, colourless, faintly odorous and slightly combustible gas; the ignition of which with free oxygen results in the second stage. The product of the second combustion is a heavy, colourless, inodorous, incombustible gas. Sulphur enters directly into combination with the oxygen of air in one proportion, namely, in the proportion of one part by weight of sulphur to an equal weight of oxygen. An incombustible, poisonous, corrosive gas, known as sulphur dioxide, results. Owing to the injurious properties of this product of combustion, native sulphur is not used as a fuel, and all fuels which contain sulphur in large quantities are rejected. Owing, then, to the small amount of this element in commercial fuels, as well as to the very low heating value of the element in itself, it is usual to neglect it in calculations about any fuel in which it may occur.

Air, which supplies the oxygen, is composed of a mixture of numerous inactive gases, of which the principal one is *nitrogen*, together with the active oxygen. The inactive gases do not, of course, undergo any chemical change in the process of combustion of a fuel, but they absorb and waste a certain amount of the heat in becoming raised in temperature. They serve a useful purpose, however, in modifying and reducing the rapidity of the combustion, and thus keeping the temperature of the burning fuel below the impracticable limit which would be reached if the oxygen were undiluted. 1lb. of oxygen is contained in every 4·35lb. of air, or, by volume, one cubic foot of oxygen is contained in every 4·76 cubic feet of air. Each pound of air occupies a volume of 13·14 cubic feet at one atmosphere of pressure and 62° Fahr. temperature, whence we may obtain the following table of the weights and standard volumes of air required to burn 1lb. of elementary fuel:—

	Hydrogen.	Carbon (incomplete.)	Carbon (complete.)
Weight of oxygen (lb.)	8·00	1·33	2·67
Weight of products (lb. in oxygen)	9·00	2·33	3·67
Weight of air (lb.)	34·80	5·80	11·60
Volume of air (c. ft.)	457·00	76·00	152·00
Weight of products (lb. in air)	35·80	6·80	12·60
Standard volumes of products of combustion (c. ft. in air)	552·00	76·00	152·00

In the above table it has been assumed that only the quantity of air or oxygen actually required for the chemical process has been supplied. In actual practice a considerable excess of air is necessary, which would make the volumes and weights of the products of combustion considerably greater. It must not be forgotten, also, that in practice the products of combustion are at a high temperature, and that their volume, but not their weight, is correspondingly increased. In estimating

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

upon the basis of the above table the quantity of air required merely for the chemical process of combustion without dilution in the case of compound fuel, it is customary to assume that the constituent elements will behave as if they were uncombined, with the single exception of the oxygen which is supposed to be combined already with its equivalent of hydrogen. Thus, if we have a fuel which is composed of C per cent. of carbon, H per cent. of hydrogen, and O per cent. of oxygen, we treat it as if it were a mixture of C parts of carbon and H_1 parts of free hydrogen, where H_1 is the hydrogen uncombined with oxygen. To obtain H_1 we must subtract from H the number of parts of hydrogen assumed to be combined with oxygen, which is equal to one-eighth of the weight of oxygen. Whence—

$$H_1 = H - \frac{O}{8}.$$

The air required for the hydrogen in one pound of this fuel will therefore be—

$$\text{Weight of air} = \frac{34 \cdot 8}{100}\left(H - \frac{O}{8}\right) \text{ lb.}$$

$$\text{Volume of air} = \frac{457}{100}\left(H - \frac{O}{8}\right) \text{ cu. ft.}$$

And for the carbon in the same amount of fuel, it will be—

$$\text{Weight of air} = \frac{11 \cdot 6\, C}{100} \text{ lb.}$$

$$\text{Volume of air} = \frac{152\, C}{100} \text{ cu. ft.}$$

Thus, the total amount of air required by the chemical process, per pound of the fuel, will be determined by the formulæ—

$$\text{Volume of air} = 4 \cdot 57\left(H - \frac{O}{8}\right) + 1 \cdot 52\, C$$

$$= 1 \cdot 52\left(C + 3\, H_1\right) \quad . \quad . \quad . \quad . \quad (34).$$

To obtain the weight of air we must divide the volume by 13·14. In a similar manner we may determine the quantity of the products of combustion, arriving at the formulæ—

Total weight of gaseous products of combustion of 1lb. of fuel in air. $= 0 \cdot 126\, C + 0 \cdot 358\, H_1$. (35).

Standard volume of gaseous products of combustion of 1lb. of fuel in air $= 1 \cdot 52\, C + 5 \cdot 52\, H_1$ . . (36).

The amount of excess of air required is determined by practical considerations of the character of the fuel and of the furnace in which it is burned. This is discussed in the chapters on the practical application of fuels. The methods of determining volumes of gaseous products of combustion and other gases at other than standard temperature and pressure will be discussed in a later section.

Heat of Combustion.—The heat which is developed by the combustion of a fuel is measured in terms of various units. One of the most common is the *British Thermal Unit* (B.T.U.), which is equal to the amount of heat required to raise one pound of pure water one degree Fahrenheit, the water being initially at its maximum density (39°·1 Fah.). The number of thermal units developed by the combustion of one pound of any fuel in air, all the heat generated being taken into account, is called the *total thermal value* of the fuel, or briefly, the thermal value. In calculating the thermal value of a compound fuel it is customary, though undoubtedly incorrect, to assume that the value for the fuel is the sum of the values for its elementary constituents, the net value of the hydrogen after the equivalent of oxygen has been subtracted being taken as the percentage of hydrogen. This has the merit of convenience, although there is necessarily an error, generally, however, of small value, introduced on account of the elements being more or less completely combined into chemical compounds. Thus, for example, a hydrocarbon gas has in actual fact a less thermal value than the separated hydrogen and carbon of which it is composed would have; less, indeed, by the amount of heat energy liberated by the combination of the elementary substances into the compound hydro-carbon which they form. As a rule, however, especially in the case of solid fuels, it is unimportant to notice this difference. The following are the approximate thermal values in British thermal units of one pound of various simple fuels:—

Hydrogen	62,000
Carbon	14,500 (to CO_2)
Carbon monoxide ...	4,325 (to CO_2)
Sulphur	4,032

Retaining the original meanings for the symbols H, H_1, C., and O, we may express the thermal value of any fuel in the following equation:—

$$(\text{B.T.U.}) = 62{,}000 \,.\, \frac{H - \frac{O}{8}}{100} + 14{,}500 \,.\, \frac{C}{100},$$

which may be simplified into

$$(\text{B.T.U.}) = 145\,(C + 4 \cdot 28\, H_1) \quad . \quad . \quad . \quad . \quad (37)$$

Evaporative Power.—It is often convenient to express the heat of combustion of a fuel in terms of the number of pounds of pure water which that heat would evaporate. It is usual to specify that the water shall be initially at the boiling point (212° Fah.), and that it shall all be evaporated from and at 212° Fah. The number of pounds which might thus be evaporated by one pound of fuel, assuming the whole of its heat could be used for the purpose, is called the total *evaporative power* of the fuel. Since it requires 966 B.T. units to evaporate one pound of water from and at 212° Fah., it follows that the evaporative power is equal to the themal value divided by 966, or roughly, divided by 1,000.

Dynamical Value.—In other cases, it is convenient to express the heat energy of one pound of fuel in terms of the mechanical work which it would do if the whole of it could be utilised. This is called the *dynamical value* of the fuel. It will be shown later that one B.T.U. is equivalent to 772·55 foot-pounds of energy. We may, therefore, obtain the dynamical value of a fuel by multiplying its thermal value by 772·55.

Coal.—The name *coal* is given to a widely-varying class of petrified organic compounds which are the remains of vegetable growth of ages long gone by. Coal usually consists of carbon, hydrogen, oxygen, traces of nitrogen and earthy matter, this last forming the *ash* after combustion. Coal also may be said to consist, in general, of volatile and non-volatile, or fixed, constituents. The volatile constituents include compounds of carbon and hydrogen — which are highly valuable — water and ammoniacal compounds — which are wasteful of the heat. The fixed constituents include uncombined carbon and earthy matter.

The destructive distillation of coal ultimately leaves a residue of solid matter, more or less porous, consisting of the fixed carbon and the ash. This is known as *coke*, and is largely used as a fuel. Coke is commercially a by-product in the manufacture of coal gas; coal being subjected to destructive distillation for the purpose of obtaining the volatile hydrocarbons in gaseous form. Being a by-product it often happens that the prepared article is cheaper than the raw material, which accounts for its common use in place of coal, especially in countries where coal is dear.

Analysis of Coal.—It will be convenient to divide the various kinds of coal into the following classes:—(1) anthracite; (2) dry bituminous coal; (3) caking bituminous coal; (4) long flaming coal, and (5) lignite. We may also consider two divisions: caking coal and non-caking or free-burning coal. The first two classes belong to the second division; the remainder are more or less caking. Free-burning or dryness in coal is generally caused by the absence or small proportion of bituminous hydrocarbons; or by the hydrocarbons which are present being of a light and highly volatile nature. Heavy, tarry hydrocarbons, and in some instances water, will cause the coal to soften and coalesce into a cake, which, however, often again becomes more or less free-burning on the

Digitized by Google

vaporisation of the volatile matter. The anthracites are a class of heavy coal, composed almost entirely of carbon, and practically destitute of hydrocarbons. They require a very high temperature for their combustion; are liable to chip into small pieces if suddenly heated; and burn with a short, lambent blue flame, or without any flame at all, developing intense heat within a zone quite close to the fuel. The free-burning bituminous coals contain from 70 to 80 per cent. of carbon, of which from 50 to 60 per cent. of the weight of fuel is fixed; and there is from 15 to 20 per cent. of volatile matter. They are capable of very perfect combustion, owing to the freedom with which air can pervade the glowing mass of fuel. The caking bituminous coals contain from 20 to 67 per cent. of volatile matter, and may have as small a quantity of fixed carbon as 10 per cent. All the bituminous coals swell considerably during combustion, and emit yellow flames of burning hydrocarbon. Cannel coal is almost free-burning, and develops long hydrocarbon flames; it has an average of 84 per cent. of carbon, of which a greater proportion is fixed than in the bituminous coals. Lignite, or brown coal, is an inferior quality of fuel, being intermediate between coal and peat. Both cannel coal and lignite develop long flames, which are liable to produce smoke unless specially dealt with. The former, which is specially used for making coal gas, is an exceptionally rich quality of fuel when burned in suitable furnaces. British steam coals are anthracitic or moderately bituminous; they develop flames of short or moderate length, and are imperfectly liable to cake. The more bituminous and long-flaming British coals, such as Boghead cannel, are most commonly employed for gas manufacture and in open grates, their use for raising steam being limited owing to their sensitive nature and liability to inefficiency.

Electric-light engineers may find it convenient to classify coals under two heads: steam coals and gas coals. The distribution of these over the surface of the globe will very much affect the growth and distribution of electric lighting. The distribution of coal is not strictly natural; for, especially in the case of steam coals, the establishment of a Government coaling station at a place where no coal naturally exists will, of course, affect the supply and price of coal at that place. Where steam coal is cheap and abundant, either by natural occurrence or by importation, and gas coal is absent or very scarce and dear, the electric light is placed under favourable conditions as compared with gas. Where, however, steam coal is not abundant nor cheap, while gas coals are plentiful, the production of coal gas is remuneratively and cheaply carried out; and electric light can only compete with gas by the adoption of generating plant capable of dealing either with the local coal itself or with the coal gas which is supplied from it. These considerations are again very much modified where there is water-power cheaply and abundantly available.

Small Coal and Patent Fuel.—Breakage of coal during transit from the workings to the furnace is usually very considerable, and it becomes a matter of great importance to be able to economically consume the large amount of small coal, or *slack*, which is thereby produced. Caking slack can be burned in ordinary grates with little difficulty, even without mixing; but dry slack must either be mixed with fuel, which will prevent it from falling between the fire-bars, or special fire-bars must be used, or else the slack must be previously made into large blocks by admixture with some binding material. Slack is largely and very economically used in furnaces which are mechanically fed, but in ordinary cases block fuel is found to give satisfactory results. Patent block fuel, which possesses a high thermal value, is prepared by mixing the powdered slack with about 10 per cent. of its weight of tar or pitch. The mixture is softened by heating, is next moulded into blocks resembling large bricks, and finally is hardened at a high temperature. This fuel requires careful treatment in the furnace, owing to the large amount of heavy bituminous matter contained in it and the consequent liability to produce smoke if not properly burned.

(To be continued.)

FRENCH CABLE ENTERPRISE.

So much has been said of late about French cable enterprise that it may not be without interest to take stock of what the French have actually done in the immediate past, and what they are seriously proposing to do in the immediate future.

The first group of colonies to benefit by the newly-awakened desire of France to lay cables were the French possessions in South America and the West Indies. In 1887, M. Granet, the then Minister of Posts and Telegraphs, brought forward a *projet de loi*, the object of which was to "create less expensive and surer means of communication with Guadeloupe and Martinique, and to release French Guiana from the telegraphic isolation in which it has remained up to this date." The scheme then proposed was to connect together Cayenne, Martinique, Guadeloupe, and Puerto Plata (San Domingo), a line to

Fig. 1.

Digitized by Google

be then extended northwards to New York, and another southwards from Cayenne to Vizeu (Brazil), and in that way the system was to be doubly connected with the general telegraph system of the world; branch lines were also to be run to the island of Curaçao, to Venezuela, and New Grenada. The French Government was to guarantee a net revenue of £40,000 for 25 years, the working expenses being estimated at £8,000, and the receipts at £86,000. Although the scheme was most favourably reported on by the Committee charged with the duty of examining it, the *projet de loi* was rejected by the Chamber of Deputies. A very similar cable network has, however, since been carried out by the Société Française des Télégraphes Sous-Marins, aided by a total annual subsidy of £8,800 from the colonies of Guadeloupe, Martinique, and Guiana, the system as at present existing being shown on the accompanying sketch map (Fig. 1). Instead of the proposed Puerto Plata-New York cable, a more modest extension has been made to Santiago de Cuba, with branch lines to Môle St. Nicolas and Port-au-Prince (Hayti). All these cables were laid in 1888-91 and have a total length of 3,754 nautical miles, their first cost aggregating close upon £720,000. The annual receipts for the first three years up to December 31, 1892, have averaged £29,450, and the working expenses £24,200, no money being set aside for renewals, and interruptions having been few during that period. During 1893 there have been numerous repairs and interruptions, and at present the Cayenne-Paramaribo, and the Cayenne-Vizeu cables are interrupted, the first since October 25, 1893. Under these circumstances it is not surprising that the *Bulletin de l'Electricité et de la Télégraphie* should remark that "it is not the results of the working of the Antilles cables by the Société Française des Télégraphes Sous-Marins that will overcome the prejudice of the French public against submarine telegraph company shares."

Detailed information with regard to the cable enterprises now in contemplation will be found in a series of articles published last December in the above-mentioned newspaper. The French possessions in the West Indies having been more or less satisfactorily connected, from a French point of view, to the general telegraph system of the world by private enterprise, it is now proposed to similarly join together the French possessions off the East Coast of Africa, the French Government this time bearing the brunt of the undertaking. The articles in question commence by detailing the various negotiations which finally resulted in the laying of the Zanzibar-Seychelles-Mauritius cable in the autumn of last year. The island of Mauritius appears to have been all along remarkably pertinacious in this matter, and when we consider the great commercial value to that colony of telegraphic communication with the rest of the world, its pertinacity is not surprising. Mauritius is situated 550 miles east of Madagascar; it has a busy population of nearly half a million; its total exports are valued at over two millions, and its total imports at a million and a-half. The one great crop of the island, however, is sugar, which is exported to the value of over £1,800,000 every year, and it was the disadvantage at which the island was placed in selling this commodity that has induced the Council of Government to make such efforts to secure a cable, previous to the laying of which three weeks at the very least elapsed before buyer and seller could complete a negotiation. So far back as 1873 a subsidy of £10,000 was voted by the colony; in 1888 negotiations took place between the English, French, and Mauritius Governments and Sir John Pender on behalf of the Eastern and South African Company. In 1890 M. de Coriolis, a member of the Council of Government, came to Europe to try and negotiate a loan of £3,000,000 for cable purposes, with England and France as guarantors. The idea was favourably received in Europe, but rejected by the colony as too grandiose. After prolonged negotiations, however, the common interests of England, India, and Mauritius resulted in a subsidised cable being laid, at the end of last year, by the English company named, between Zanzibar and Mahé (Seychelles), a distance of 1,172 nautical miles, and between Mahé and Port Louis (Mauritius), a distance of 1,115 nautical miles (*see* Fig. 2).

France, with its important possessions thus left out in the cold, is now eager to make up for lost opportunities. A short length of cable of 170 miles would indeed suffice to place Réunion in telegraphic connection with the rest of the world *viâ* Mauritius and the Seychelles, but a more ambitious scheme is on foot. The present intention of France is to make Mozambique, where landing rights have been conceded by Portugal to France, the point of junction between its colonial cable system and that of the English companies. From Mozambique the idea is to run a cable to Mayotta, thence to Nossi Bé, and thence to Diego Suarez and Tamatave. The total length of this cable would be 1,239 nautical miles, and the estimated cost is £182,000.

"Such," says the *Bulletin de l'Electricité*, "is the first cost of the Madagascar cable system, on which interest at the rate of $4\frac{3}{4}$ per cent. will have to be guaranteed, as well as a renewal fund to renew the cable within 25 years. If we add for maintenance and repairs a sum of 65fr. per kilometre, in accordance with the data upon which this item was based in connection with the Zanzibar Seychelles-Mauritius cable, we shall require a minimum annual revenue of 462,500fr., no allowance being made for the working expenses of the six stations, which cannot be estimated at less than 150,000fr., and which

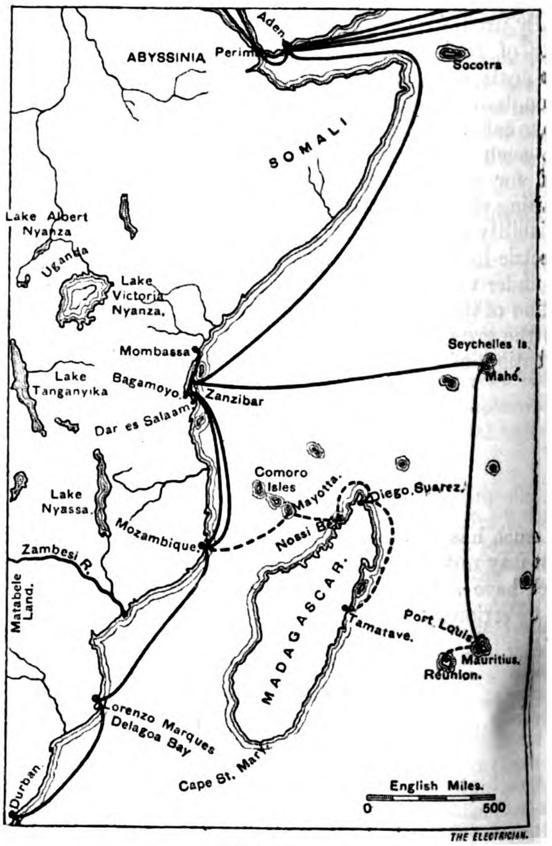

FIG. 2.

we cannot hope will be covered by the Madagascar message revenue, which it is difficult to estimate, and for which there are no data to go upon except the returns for 1891-92, which give an average of 4,700 words per annum. If Réunion is to be connected to Madagascar, the return, at the same rate as above, upon the capital outlay of 1,690,000fr. necessary for this 845-kilometre cable, will call for a revenue of 168,000fr. However, as the connection of Réunion with the general telegraph system of the world is almost entirely a matter of commercial interest, it would suffice to connect it up by way of Mauritius, which would involve a much smaller outlay. Whatever may be the decision as regards the size and nature of the system of cables which is to be laid down in Malagasian waters, it is impossible to attach too much weight to the imperious necessity of maintaining and repairing it in the most effective manner; if this be not done, all the expense of establishment will be thrown away."

The only remaining French cable to be mentioned is that just laid between Queensland and New Caledonia, of which the *raison d'être* is certainly not commercial.

THE BLACKPOOL ELECTRIC TRAMWAY.

The following summaries of the Reports on the state of the Blackpool Electric Tramway, presented to the Town Council by Mr. J. Hesketh (borough electrical engineer), and Messrs. T. Parker and Holroyd Smith, will be read with interest:—

Mr. Hesketh states that the engines and boilers are in good average condition, only the governors requiring renewal, and in his opinion there are many years' work yet to be got out of them. With regard to the belting and shafting it is pointed out that the engines drive on to a countershafting by means of ropes, and from the countershafting to the dynamos by means of two link leather belts. The ropes on one engine have had to be replaced, the old ones being worn out. Before replacing them it was occasionally necessary to stop one engine and start the other when ropes broke. These stoppages were on an average three to five minutes in duration. On September 9, 1892 (the first day on which the Corporation controlled these tramways), the main belt of No. 1 dynamo broke. Since that date to about August, 1893, one or other of the belts have given trouble on an average every ten days. These did not, however, cause stoppage of the cars, one dynamo being able to do double duty until the necessary repairs were carried out. It was, however, in the early part of September last that the more serious trouble with the belts began, and on August 24th Mr. Hesketh reported to the Committee that the belts were rotten and "running under protest." However, had the load on the dynamos been regular, even though heavy, the belts and all the parts would have borne the strain safely. It was owing to the excessive and *irregular* strains that the trouble arose, and that the care of these belts became a dangerous occupation. The hole in the roof of the engine-room, Mr. Hesketh remarks, still stands as a testimony to one of the many breakages. The dynamos are in a condition equal to that in which they were handed over to the Corporation, with the exception of the commutator of one machine, which is worn out. No stoppage has been caused by this. Trouble, however, has been experienced owing to the breaking of armature connections. This is due almost entirely to the heavy strains arising from the "short circuits" and "cut outs." The motors have run well, with one or two exceptions, considering their condition when handed over to the Corporation. The field-magnet windings have had to be renewed in some cases, and repaired in almost all. In one or two cases wires had been ripped bodily off the framework of the motor by the steel end of the collector rising and catching the motor on a "break away" happening at a narrow part of the channel. The wiring in the cars has given considerable trouble, and in most cases has been renewed. The old joints had been made with salts as a flux, and even though the action was slow it was certain, and at the end of 7 to 7½ years *all* the joints so made became useless. This, remarks the Borough Electrical Engineer, is interesting, as giving the life of a badly made joint, but as an experience on taking over the old Company's system it is disheartening. In discussing the question of the centre channel and collector, it is stated that the cover rails being fixed, it becomes an impossibility to examine the connections and insulators frequently. Nor can the whole of the insulators be cleaned more than once a year, and even on this occasion they cannot be freely handled. The freedom with which dirt enters the channel is well known. In removing it, it is impossible to avoid leaving some amount round the insulators. In the course of a month or two this becomes a serious consideration, and at the end of twelve months the leakage of the first few hours of the day is sufficient to drive 10 to 20 cars. Then the cover rails expand and contract with varying temperatures, supporting-chairs in many instances break, and the slot which should be $\frac{1}{2}$in. diminishes to $\frac{3}{8}$in., or even less. It should be borne in mind that through this slot has to pass the current-carrying conductor to the motors, and that this *must* be well insulated. To make an efficient collector for this system to pass through a $\frac{3}{8}$in. slot is impossible. By an *efficient* collector is meant one that will run a week without causing any trouble in any kind of weather. During the past year there have been days on which as many as 24 to 30 collectors have been sent into the shed for repairs.

It is my firm conviction, says Mr. Hesketh, in conclusion, that if the channel construction had originally been such as to admit of a wider slot with more perfect insulators and collectors, the trouble we are at present experiencing would never have occurred. And if the Committee is desirous of making the present system run, the only manner by which, in my opinion, it can be done, is by attention to these points. It would not be justice to the staff, who have had to bear the brunt of these troubles, if I did not here record how well they have striven to meet the difficulties as they arose. I am convinced that had not they in my department, and the Traffic Manager with his staff in his, done their level utmost up to, and more especially since August last, the complaints would have been, if not more frequent, at least more justifiable.

Mr. T. Parker reports:—The channel and conductor are in better condition than I expected, and there are no difficulties other than have had to be encountered by the Company in working the line. At a number of the crossings the parts have worn and fallen out of form. These need a little planing or fitting, and the road at these points will require to be adjusted. The channel in many parts has closed in, due to the weight of the traffic. To remedy this the steel pieces will have to be taken up on the outmost convenient side, to give the slot a minimum width of $\frac{5}{8}$. At the same time the whole of the insulators and conductors could be examined and corrected. The wood pavement has closed the gauge of the line in some parts, and this will always be a trouble unless provision is made to permit of the expansion of the pavement towards the footway, and prevent the closing in of the guage. The electrical machinery at the generating station and the car motors have fallen into a sad condition of delapidation. Considering the whole problem in the interests of the Corporation, there seems but one line to follow—the overhauling of the road to bring it up to a working condition, and the overhauling of the motors and car gearing so that they will work out their duties until the larger problem can be reconsidered when the extensions are decided upon. I would, therefore, suggest that one machine should be put down, which shall be a suitable unit for driving the tramways when the larger scheme is adopted, and this machine be up to date, powerful enough to use the power of both present engines, and sufficient in itself, with a spare armature as a reserve, to work the tramway as it now is, until the extension and system shall have been determined, when the spare armature could be fitted to a pair of magnets making two machines which would be sufficient power to deal with the proposed extension, whilst for the temporary arrangement the spare armature would be a stand-by in case of anything happening to the other armature.

Mr. Holroyd Smith says: The tram rails and channel steel, considering the time the line has been in use, are in very fair condition, and may be considered good for many years to come. With few exceptions, all the rail points need attention; some of them are in a bad condition, and will require renewing. Where wood paving has been employed, the gauge of the rail was tight, whilst in other places the gauge was wide, the variation between the two being about three-quarters of an inch. This is distressing to the car wheels. Some hydrants of the salt water supply were leaking, the water finding its way into the electric channel mostly at the rail crossings, which are in a defective condition. Many channel chairs were broken, probably by the heavy load taken over the road for supplying materials for the tower and south pier. In some places the slot was its original and correct width, but considerable difficulty has been experienced in maintaining it in others; in many places the slot is too narrow for the safe passage of the collector. Nearly all the caps which cover the nuts holding the steel channel in places were broken. The drivers informed me that the contracted channel caused them much trouble; in many instances the collector jammed, tilted up, and the hook ripped open the field wires of the motors. This has evidently resulted from an attempt to force the collector through a tight place instead of correcting the slot; for the collectors are so designed and should be so attached to the car that when an obstruction occurs they will be automatically released and cause no damage. It has been a mistake to abandon this practice. The majority of the sump-holes were full of mud; in some the outlet was choked. Several were rusted fast, and, presumably, have not been opened for some time. A few sump-holes were fairly clear of mud, from which it may be reasonably inferred that with due attention the others might have been kept the same. A number of insulators were broken or defective; none were quite clean. All the copper tubes that have been in for any length of time are corroded where the wooden stud of the insulator supported them, due to electrolitic action, and the corrosive action of salt water. The present shape of insulator with the wooden studs was adopted notwithstanding my emphatic protest and prediction of the present result. Only those tubes that have recently been fixed are fit to remain; the rest are so corroded they should be removed. I was only able to find six U couplings; of these, three were in fair condition, the rest bad and in a condition to account for a large percentage of leakage.

The condition of things in the shed was deplorable—dirt and confusion where everything should be clean and in order. The tramcars are mostly in a poor condition; in many cases the "horn" plates are severely strained, I noticed broken wheels and a broken axle. Two open summer cars that have been little used, and apparently in good condition, are littered with old iron and rubbish. The motors have been removed from the cars; they were somewhat carelessly stored in the dynamo room; they were in a dirty condition; in every one the lids were missing from the oil cups, in some the commutators were worn out and the field windings damaged. Many parts of gearing were lying about the shed, but no set complete. I found that my original design of gunmetal invert wheels, held in a cast-iron casing by wooden blocks to deaden the sound, had been abandoned, and cast-iron inverts used instead; cheaper certainly, that is all. The dynamos were covered

Digitized by Google

with moisture and dirt, to the risk of destroying their insulation; the commutators are worn out, and the connections to the armatures are defective in many places. Still, I consider them serviceable machines, and, if put and kept in order, fully able to supply electric energy sufficient for all the cars that can be run upon the existing line.

By sending a current into the line it was found that the insulation resistance was little more than one ohm. While recognising that owing to the saline moisture of the road, the frequent sea-flooding and sand-storms, Blackpool is, perhaps, the most difficult place that could be selected for the construction of an electric tramway with the conductors underground, and, further, that the line was the first of its kind, there being no precedent for guidance, and that the conditions imposed were difficult to fulfil (that requiring so narrow a slot being specially to be regretted), yet the line as originally designed and constructed has for many years been successfully worked, though it requires painstaking and skilful attention. To restore the line to its original state, all the existing insulators with wooden studs would have to be removed and another type used. The number of insulators would be 2,000 instead of 9,000, as now, and the insulation of the line would be proportionately increased, and the excessive loss through leakage which now occurs would be reduced to a minimum. Though the existing motors are in a bad condition I see no reason why they should not, at a small expense, be put into a thorough state of repair. The whole of the material at the shed requires overhauling. For the present the tramway working should not be combined with the Electric Lighting Station. The plant when put into proper order is amply sufficient for the existing line and the number of cars that can be run thereon.

THE PUBLIC SUPPLY OF ELECTRICAL ENERGY: ITS COST AND PRICE.*

BY A. BROMLEY HOLMES, M.INST.C.E.

Three years ago the author had the privilege of reading before this Society a Paper descriptive of the Liverpool Electric Supply Company's stations, in which the plant used was described and the subject dealt with solely from an engineering point of view. The object of the present Paper is to regard the distribution of electrical energy from what may be termed the commercial point of view; that is to say, to deal with the items forming the cost of production and the considerations which decide the price and method of charging for the supply. Before proceeding with his subject the writer would desire to place on the records of this Society a few figures with regard to the progress of the local company referred to above since the date of his previous paper. At the end of the year 1890 the number of lamps supplied was 12,000, the length of mains 20 miles, the maximum output 4,000 amperes. At the present time there are 25,000 lamps supplied, the length of mains is 30 miles and the maximum output over 9,000 amperes. A new central station has been constructed in Lark Lane for the residential district of Sefton and Princes Parks. The system of supply is the same as in 1890, such modifications in minor details having been made from time to time as experience has shown to be advantageous.

In dealing with the cost of production and selling price of electrical energy it is convenient to adopt as the basis of calculation the Board of Trade unit. This unit is equivalent to a current of 10 amperes at an electromotive force of 100 volts flowing for a period of one hour. It represents approximately the amount of electricity consumed per hour by two arc lamps, each of 1,000 c.p., or by eighteen 16-c.p. incandescent lamps. The items which form the cost of production and distribution may be divided broadly under three heads: (1) Coal, oil, water, wages and repairs; (2) Rent, taxes, office expenses and management; (3) Depreciation and interest on capital.

To obtain figures which represent practical work the author has analysed the working costs of eight of the largest supply companies, which distributed in the year 1892 a total of 7,259,000 units, and for which companies the various items of cost average as follows:

Coal	1·14	pence per unit.
Oil, water, stores	0·19	" "
Wages	0·87	" "
Repairs	0·45	" "
Total works costs	2·65	
Rents, taxes, &c.	0·18	pence per unit.
Management and office expenses	0·73	" "
Total expenses	0·91	" "

In dealing with the third item—viz., depreciation and interest on capital—the author finds that the expended capital of the eight companies referred to averages 57 pence per unit distributed. Assuming a charge of 5 per cent. for depreciation and 5 per cent. for interest, a total of 10 per cent. on the capital expended, or 5·7 pence per unit, may be taken for the purpose of the present calculation. The total costs would then stand as follows:—

Works costs	2·65	pence per unit.
Other expenses	0·91	" "
Depreciation and interest	5·70	" "
Total	9·26	" "

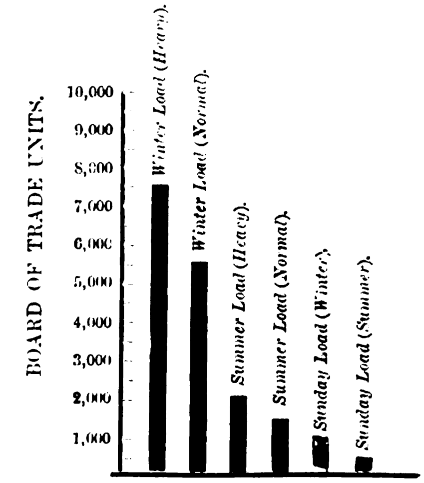
The average price obtained by the eight companies in 1892 was 6·45 pence per unit, and although this price afforded a good margin beyond the actual cost of works and management, it is obvious from the above figures that depreciation and interest were not sufficiently provided for. The figures for the year 1893 are not yet available, but no doubt they will be somewhat more favourable than the above, though the exceptionally fine autumn, the greater care exercised by consumers in the use of the light, and, lastly, the coal strike, are causes which have prejudicially affected the revenue of electric supply companies during 1893.

It may be of interest to examine the items of cost *seriatim*, with the view of considering the conditions which affect them and the possibilities of reduction.

First to take the coal bill. The greatest difficulty that supply station engineers have to deal with is the great variation of load—a variation that is often extremely rapid and not unfrequently takes place at quite unexpected periods, as, for example, in the case of a thunderstorm in summer or a sudden fog in winter. With a varying load it is practically impossible to run the engines under the most economical conditions. The efficiency of a modern combined engine and dynamo (that is to say, the ratio of electrical output to indicated horse-power) may be almost 90 per cent. at full load, whereas at one-third load it will only be about 60 per cent. The lesson to be drawn from this is that the smallest set of plant in a station should not have a greater output than (say) one-tenth of the maximum output of the station, and that generally the size of plant selected as a unit should be chosen with due regard to the load diagram of the station, so that the engines may always be run fairly well loaded. The following figures will give some idea of the variations of load of stations supplying electricity almost entirely for lighting purposes. During the past year the output of the Liverpool stations, with about 24,000 16-c.p. incandescent lamps (or their equivalent) connected to the mains, has been (*see* Diagram 1)*—

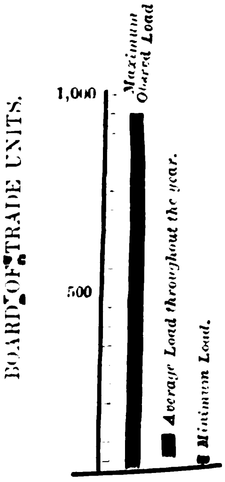
For a normal winter day	5,500	units.
" heavy " "	7,500	"
" normal summer day	1,400	"
" heavy " "	2,000	"
" Sunday in winter	1,100	"
" " " summer	520	"

DIAGRAM 1.



Output of Liverpool Central Stations during Summer and Winter.

DIAGRAM 2.



Maximum, Minimum, and Average Load of the Liverpool Central Stations.

The rate of output has varied as follows:—On a heavy winter day from 912 to 29 units per hour, with an average of 313 units throughout the 24 hours; and on a normal summer day from 143 to 11 units per hour, with an average of 59 units for the 24 hours. The maximum load during the year has been 929 units per hour and the minimum 6 units, the average load throughout the year being about 110 units per hour. (*See* Diagram 2.)

[* We have taken the liberty of giving our readers a graphic representation of Mr. Holmes' figures.—ED. *E.*]

* Abstract of a Paper read before the Liverpool Engineering Society.

Mechanical stokers render it possible to burn a cheaper class of fuel than is possible with hand stoking, but fuel should be selected, not necessarily at the lowest price per ton, but of such a class as is found by experiment to evaporate the most water for a given expenditure. Sufficient consideration is often not given to the fact that in an electric light engine room cleanliness has a real money value. Wages are an important item of expenditure. The men employed must be fairly paid, and economy must be sought by making all the working conditions of the plant as simple as possible, so as to avoid any unnecessary labour.

In the earlier portion of the Paper 10 per cent. has been put down for depreciation and interest. Depreciation naturally varies very much with the various items of capital expenditure. A percentage that would be reasonable for boilers and moving machinery would be excessive for buildings and for street mains. The exact rates of depreciation on such articles as meters and accumulators have yet to be fixed from experience. As far as can be seen at present an all round rate of 5 per cent. for depreciation is a fair basis for the present calculation. With respect to the rate of interest a return of 5 per cent. will attract the necessary capital for electric light and kindred undertakings when carried on by companies. Municipal corporations can borrow at lower rates, but in compensation for cheap money they would appear to suffer from disadvantages which prevent them from carrying out their work more economically than other people.

A reduction in the cost per unit under this head must be sought in the smaller amount of locked up capital per unit generated that may be looked for as the demand for electrical energy increases, not only for lighting, but also for power purposes. As far as the writer is able with his present experience to form an opinion, there is reason to expect that the costs given above may gradually be reduced to the following rates :—

Works costs	1·5	pence per unit.
Management	0·5	" "
Depreciation and interest	3·0	" "
Total	5·0	

or little more than half the figure arrived at from the returns of the eight companies referred to above for the year 1892.

As regards the selling price of electrical energy in the earlier Provisional Orders granted by the Board of Trade, the maximum price to be charged was fixed at 1s. per unit. In the more recent orders the maximum rate has been reduced to 8d. The Electric Lighting Acts forbid any undue preference in favour of any particular consumer, and it is therefore necessary either to make a fixed charge to everybody or to adopt some system of sliding scale that will be equally just to all classes of consumers. It is obvious that a consumer who uses 1 H.P. for 1,000 hours per annum is a much more desirable customer than one who uses 10 H.P. for 100 hours per annum, for, although each of them uses the same total quantity of energy, the plant required at the station to supply the former customer is only one-tenth of that required to supply the latter. In the Liverpool Electric Lighting Licence issued by the Board of Trade in 1888 this fact was recognised, and a sliding scale clause was inserted. More recently the Manchester Corporation have offered their consumers either the statutory rate of 8d. per unit, or, as an alternative, a fixed charge of £3 per quarter for every unit per hour consumed when all the lamps or other consuming devices are in use, and 2d. per unit for each unit supplied as measured by meter. Both the Liverpool and Manchester methods recognise the value of the long-hour consumer and seek to encourage him by a differential rate of charge. What the result of the Manchester system may be remains to the seen; but in Liverpool, after four years' trial of the sliding scale, it was found desirable to abandon it and to adopt in its place a uniform rate of charge.

Some supply companies offer a discount to consumers who use more than a stated quantity of electricity, irrespective of the rate at which that quantity is consumed. Such a system would seem to press unfairly on small consumers, and to compare unfavourably with the Liverpool and Manchester sliding scales, which give equal advantages to all classes of users. Again, some companies offer a discount to consumers who pay their accounts without application within a specified time. This plan deals out a kind of rough-and-ready justice by making those consumers whose accounts have to be collected with more or less difficulty pay the cost of collection.

The simplicity of a fixed rate of charge has much to recommend it, and the interests of the greatest number of consumers are probably best secured by a system of uniform charge rather than by one which gives advantage to a limited number of consumers at the expense of the rest.

This Paper so far has only dwelt with the cost of producing and the price for selling a unit of electrical energy without any reference to the amount of light that can be produced by it. The price charged for electrical energy for lighting purposes is so constantly compared with that of gas, that a few figures of comparison may, in conclusion, perhaps, be of interest. A gas burner consuming 5ft. of gas per hour will, with Liverpool gas (which is of higher illuminating power than any other public supply of gas in the kingdom), produce a light of 20 candles. Experiments made in London and elsewhere have given much less favourable results, and probably even in Liverpool the average house gas burner in average condition does not afford more than 16 c.p. for the consumption of 5ft. of gas per hour. Assuming gas to cost 3s. 4d. per 1,000, the above 16-c.p. burner would cost two-tenths (·2) of a penny per hour. An ordinary incandescent lamp consumes energy at the rate of 3½ watts per candle, and consequently a 16-c.p. lamp consumes 54 watts, and with electricity at 7½d. per unit costs four-tenths (·4) of a penny per hour, or just twice the cost of gas. Incandescent lamps consuming 3½ watts per candle may be expected to have a life of about 1,000 hours, and when lamps cost 3s. 6d. each a reasonably long life was an important factor. Now, however, that the patents have expired and lamps can be obtained at about one-fourth the cost it may pay to run them at a much higher efficiency with a shorter life. Lamps can even now be made which consume only 2½ watts per candle-power, and when such lamps can be shown to be fairly durable they will no doubt be largely used. Assuming that in the not very remote future electrical energy can be supplied at 5d. per unit the cost of a 16-c.p. lamp would be two-tenths (·2) of a penny per hour, or just the same as the present cost of gas.

LONDON CHAMBER OF COMMERCE.

ELECTRICAL TRADE SECTION.

An adjourned meeting of this body was held at Botolph House, Eastcheap, on Monday last, Mr. Emile Garcke presiding.

The Secretary (Mr. Kenric B. Murray) intimated that a meeting was held at the Mansion House the preceding week, the Lord Mayor being in the chair, at which it was decided that this Chamber, in conjunction with half-a-dozen gentlemen, appointed then as a committee, should act as an English Commission over the English section of the forthcoming Exhibition at Antwerp. Fairly satisfactory arrangements had been made, inasmuch as the British Consul General had, with the sanction of the Foreign Office, consented to act as British Commissioner from motives which were purely disinterested, beyond endeavouring to develop British trade in Antwerp, other parts of Belgium, and the Continent generally. The Consul's action, apart altogether from the financial side of the question, would be under the joint supervision of the said Committee and the Chamber of Commerce. They regarded the Antwerp Exhibition to some extent as an experiment from which they might learn a good deal to guide them in the future, when larger Exhibitions might be held in London and elsewhere. They had printed documents in regard to applications for space, the charges to be made for exhibits, and other such information, which he would be glad to place at the disposal of all concerned; and they would transmit to Antwerp all such applications, and acquaint the applicants with the replies received therefrom. They would gladly receive the co-operation of any trades, and particularly of those connected with the Chamber.

The Chairman said that he had approached several large electrical firms on the subject, but as far as he could gather they did not seem to show any inclination to send exhibits to Antwerp, but he thought it was only right that the Chamber should issue a circular to the members bringing to their notice the opportunities which they have of being represented at the Exhibition. He did not know of anything else that could be done.

Mr. Henry Edmunds said that one of the great difficulties in connection with all such exhibitions was that unless exhibitors were unanimous and pulled together it was found that there were only one or two individuals who spent a great deal of money who really reaped any return for their outlay.

The Chairman said there was no doubt that we were not improving our trade by abstaining from putting in an appearance at these exhibitions, but it was very hard that the onus should be thrown upon individual firms who found it very difficult to make both ends meet.

It was then resolved to issue the circular as suggested by the Chairman.

The Chairman said that the next question on the agenda was the report of the action of the Traction Committee. It had been suggested by several members of the section that it would be interesting to them to know what was the result of the suggestion which was discussed at a former meeting to constitute a special committee for the purpose of representing interests which were, if he might use the term, antagonistic to some extent to those of another part of the section. That arrangement had been carried out very satisfactorily, and it was of interest from this point of view that it showed that the London Chamber of Commerce afforded opportunities for the interests of other sections being adequately and fairly represented. They had been able to bring about an organisation

Digitized by Google

of interests which was necessarily very satisfactory to those who were concerned in the matter, and which, he took it, had not in any way prejudiced the interests of the other members of the section as such. They were able by this organisation to raise a sufficient amount of money to consult counsel and to attain generally the objects which they had in view. It would be gratifying, therefore, to the section to know that if the occasion should arise in future there would be no difficulty in arranging with Mr. Murray so that they would be able to raise money, and apply it to their own purposes, and to have their own executive officers.

Mr. BEAUMONT asked whether there was to be any report from the Traction Committee, and whether the work for which it was formed has been accomplished.

The CHAIRMAN replied that the work for which it was formed had not been accomplished, but the Board of Trade had now the matter in hand, and had been drafting regulations in pursuance with the recommendations of that Committee, and until those regulations were completed the work of the committee could not be carried out.

This was all the business, and the members separated.

THE MAGNETIC PERMEABILITY OF OXYGEN.*

BY R. HENNIG.

The author utilised in these researches the method of Toepler, who by one observation determines the difference in the pressure exerted by two gases under the influence of a magnetic field, his principle being as follows: A glass tube of small bore is taken and bent into a slight elbow, and a small quantity of a liquid is poured into it in such a manner as to form a short thread of liquid separating the arms of the tube, the bend being, of course, at the lowest point. If the tube be now placed in a magnetic field, in such a manner that the liquid is in the centre and the limbs project, then if one limb is filled with a gas of greater magnetic permeability than the other, the pressure on the liquid will be greater on that side, and the thread will move up the tube towards the opposite side, and the amount of displacement is a measure of the permeability of both gases which can be determined in absolute measure. For call these permeabilities μ_1, μ_2, that of the liquid μ_0, and let them be in a field of strength H, and let the pressure on each side be p_1 and p_2 along the tube, then

$$p_1 = \frac{\mu - \mu_0}{2} H^2 \qquad p_2 = \frac{\mu_2 - \mu_0}{2} H^2.$$

Whence we get the equation to the force,

$$p_1 - p_2 = \frac{\mu_1 - \mu_2}{2} H^2,$$

producing the force on the thread of liquid. This can be equated to the force produced by the displacement

$$P = l \, . \, a \, . \, s,$$

Where l is the horizontal displacement in centimetres and the angle at which the limits are inclined, in circular measure, and s the specific gravity of the liquid in degrees per c.c. Thus we get the formula—

$$\mu_1 - \mu_2 = 2 \, l \, a \, . \, s / H^2,$$

which, it will be noted, is only true for a uniform field. A difference of pressure due to want of uniformity in the field may be detected by observing the deflection, all other conditions being identical when the limits are filled with the same gas; first for one of the gases under examination, and then for the other. Calling these deflections l_1 and l_2 the formula becomes modified into—

$$\mu_1 - \mu_2 = 2\,(l - l_1)\, a\, s / {H_2}^2\,;$$

or

$$\mu_1 - \mu_2 = 2\,(l - l_2)\, a\, s / {H_1}^2\,;$$

in which case H_1 and H_2 are the strengths of field at the surfaces of gases 1 and 2 respectively.

The author's chief object in these researches has been to determine the permeability of oxygen under various pressures, and his chief difficulty appears to have been in the sufficiently accurate determination of the magnetic field. He therefore goes into detail on the subject, chiefly of three methods; first, the optical method, by determination of the amount of rotation of the plane of polarisation, which is accurate, but has the disadvantage of requiring a darkened room; secondly, the induction method by slipping a coil of known area quickly into the field. This is the most generally useful method, but the mechanical details of the apparatus prevented its being always used. Thirdly, the bifilar galvanometer method of Weber, used by Kohlrausch for determining the horizontal intensity of the earth's field, the principle of which is as follows: a coil of area F is hung by a bifilar suspension (of controlling force D), which conveys a current, C, to the coil whose axis is horizontal, and whose plane is parallel to the lines of force of the field. The horizontal deflecting moment is H F C cos a, where H is the field and a the angle of deflection, and the controlling torque is D sin a; so that

$$H = D \tan a / F\,C.$$

This method has many advantages, chiefly the great range owing to the various values which can be given to C, the possibility of measuring the current and the deflection a very accurately by scale and mirror. The coil may have a copper damper, and so come to rest at once; and the whole thing may be made excessively small. By careful measurements the field was determined to well within 1 per cent.

The results of the observations, which up to date are confined to a comparison of oxygen and air, are summed up in a table, of which the following is an abstract. The author considers that, broadly speaking, they show that the pressure varies with the density of the gas and the square of the field, and that the ratio of the permeabilities should be a constant, the differences in the last column he puts down to errors of observation. The mean error is 3½ per cent., and the probable error of the result may be taken at 1 per cent.

Table II. contains a summary of the values obtained by other observers, and by the author. Note that for every degree (at about 20deg.) rise of temperature, the permeability falls by 0·7 per cent.

THE EFFECTS OF LIGHT ON THE ELECTRICAL DISCHARGE.*

While engaged on his classical experiments, Hertz noticed that the appearance of the discharge between the two terminals of the oscillator was greatly changed upon the spark gap being illuminated by the light coming from another spark. This change was not due to an electrical action of the sparks, for it was equally well produced by other sources of light, such as the electric arc and burning magnesium, while all effect immediately ceased on interposing a plate of glass. Since the time when the above observations were made, many experimentalists have investigated this subject, and have obtained rather divergent results. In most cases the source of light employed has been the electric arc formed between carbon rods, though, with a view to increase the proportion of ultra-violet rays emitted, Bichat and Blondlot used carbon rods with aluminium cores, while Righi used a zinc rod for one terminal. Other observers have used the spark of an induction coil passing between terminals of copper, zinc, or aluminium. While Hertz had only noticed that the illumination of the discharging knobs increased the facility with which sparks passed, Wiedemann, Ebert and Hallwachs found that it was only when the negative terminal was illuminated that this effect took place. More recent observations by Branly have led to this view being modified, for he finds that on illuminating a piece of zinc by the sparks of a large induction coil produced between aluminium terminals, if the source of light is sufficiently near to the plate, the loss of charge is nearly as rapid for a positive as for a negative charge. On increasing the distance between the spark and the charged plate the decrease in the rate of

* Abstract from *Wied. Ann.*, Vol. L., No. 11, p. 485.

* From *Nature*.

Digitized by Google

loss of charge is much more rapid for positive than for negative charges, and thus at some distance from the source of light the negative charge is the only one which is appreciably affected. Hence radiation of certain kinds increases the rate at which a positively charged body loses its charge, just as in the case of a negative charge, but the rays which are active in the case of positive electricity are absorbed by even a small thickness of air, while those rays which are unabsorbed are still able to accelerate the discharge of a negatively charged body.

After having made a series of experiments in air at ordinary pressures, Stoletow, on the one hand, and Righi, on the other, have investigated the influence of pressure on the phenomenon, and have both found that the effect increases with a decrease of pressure, while Stoletow has shown that if the rarefaction is carried to the extreme limit there exists a pressure, after which the effect decreases as the pressure is further diminished.

An experiment of Bichat's seems to show that the loss of electricity is due to convection currents, and this view has been further strengthened by Righi, who placed a plate of ebonite covered with tin foil on its upper side above a brass plate on which some figure, such as a cross, had been traced with varnish so that the plate was protected at these points from the effect of the illumination, the active rays being absorbed by the varnish. The negative pole of an electric machine was connected to this plate, the positive pole being connected to the tin foil, and the light of an electric arc allowed to fall on the under plate for a few seconds. The plate of ebonite being removed and powdered over with a mixture of sulphur and red lead a yellow cross on a red background was obtained of the same size as the one traced on the brass plate. As the sulphur attaches itself to those parts of the plate which are positively, and the red lead to those which are negatively charged, it follows that the parts of the lower plate which were not protected by the varnish have lost some of their negative charge, which has been carried on to the ebonite plate, and that this displacement has followed the lines of force of the electric field between the plates, which are in this case perpendicular to the two plates. This conclusion is further strengthened by observing that, if the electrified particles which escape from the lower plate are prevented, by means of a screen, from reaching the ebonite, a shadow of the screen is obtained.

The explanation that this convection is caused by the molecules of gas which, after being in contact with the body, become charged and are repelled, is hardly satisfactory, and the experiments of MM. Lénard and Wolf seem to show that it is particles of dust which carry the charge, for they suspended an insulated plate of metal in a box filled with air which had been carefully freed from dust. A plate of quartz fixed in one side of this box allowed the light from an electric arc to fall on the metal plate, while a stream of some vapour could be introduced through a side tube. Under these circumstances the vapour was condensed on allowing the light to fall on the plate if it was uncharged or negatively charged, while if the plate was positively charged no condensation took place. As it is known that a given space can become supersaturated with vapour when no dust is present, but that the introduction of the least trace of dust causes an immediate condensation, it appears that when a body either uncharged or negatively charged is illuminated it gives off some dust, and that the loss of charge is due to this dust. Further particulars of the work which has been done in this subject are given in a Paper by M. Blondin in *Electricité*, p. 313, 1893.

EXPERIMENTS ON A NEW RESISTANCE MATERIAL, "KRUPPIN."*

Messrs. Krupp and Co., of Essen, have recently brought out a new material for resistances which they call "Kruppin," the chief peculiarity of which is its high specific resistance. Herr Dettmar, of Frankfurt, has sent the results of some experiments on it to the *Elektrotechnische Zeitschrift*, from which it appears that the resistance varies with the hardness of the material, but becomes practically constant after the wire has been once annealed by heating to redness by means of a suitable current. The specific resistance is about $82 \cdot 9 \times 10^{-6}$ ohms per cc., which is about 50 time that of copper.

The temperature coefficient, measured between 75° and 15° centigrade, had an average value of 0·13 per cent. per degree. The author gives the results of a series of experiments on the amount of spacing in spiral coils of given diameter for which the rise of temperature is a minimum, or rather for which the current required to produce a certain temperature is a maximum, and his results in these cases are capable of general application. They are as follows: the coil heats least (when 12mm. in diameter) 2·2mm. wire, 15 turns per decimetre; 1·0mm. wire, 35 turns per decimetre; with a coil (of 2·2mm. wire) 18mm. in diameter, 18 turns per decimetre; with a coil of 6·0mm., and the same size wire, the turns had almost to touch one another. In the 13mm. coil the best result is attained by having the spaces equal to twice the diameter of the wire.

Finally, the results as to carrying power for various wires are given by the accompanying table; the limit of temperature allowed being that at which the wire "spits" when touched with the damp finger.

Diameter of wire.	Resistance.	Current carried by spirals.			
		In air.		On insulating cylinder.	
		Cnstnt.load	1 min. load.	Cnstnt.load	1 min. load
mm.	Ohms pr mtre	amps.	amps.	amps.	amps.
0·5	4·23	1·0	2·0	3·0	6·0
1·0	1·058	3·0	6·5	9·0	20·0
1·6	0·413	5·5	15·5	14·5	31·5
2·0	0·264	7·5	23·0	18·0	37·5
2·5	0·1690	10·5	34·0	21·2	43·5
3·0	0·1175	14·0	45·0	23·5	48·5
4·0	0·0661	21·5	75·0	—	—

All the above results apply to the best spacing for each spiral. "Kruppin" is also manufactured in sheets, but the author's experiments on this subject are not yet completed.

* Abstract from the *Elektrotechnische Zeitschrift*, December 15, 1893.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 2nd.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Annual Meeting at 25, Great George-street.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street, S.W. Experiments illustrative of the Paper on "Multiphase Currents and their Applications," read at the last meeting, by C. V. Drysdale.

ROYAL INSTITUTION.

9 p.m Evening Discourse: "Bookbinding: its Processes and Ideal," by T. J. Cobden Sanderson.

MONDAY, February 5th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. "The Detection and Measurement of Inflammable Gas and Vapour in the Air," by Frank Clowes, D.Sc.

TUESDAY, February 6th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Monthly ballot for members. The following Paper to be read: "The Transport of Petroleum in Bulk," by Boverton Redwood.

WEDNESDAY, February 7th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "Automatic Balance of Reciprocating Machinery, and Prevention of Vibration," by W. Worby Beaumont.

THURSDAY, February 8th.

SOCIETY OF ARTS.

4:30 p.m. Meeting of the Indian Section at the Imperial Institute. The following Paper will be read: "Telegraphic Communication between England and India: its Present Condition and Future Development," by E. O. Walker.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. The following Paper will be read: "Some Notes on the Electric Lighting of the City of London," by Maj.-Gen. C. E. Webber, C.B., M.Inst.C.E.

FRIDAY, February 9th.

PHYSICAL SOCIETY.

5 p.m. Annual General Meeting. The following Paper will be read: "The Viscosity of Liquids," by O. G. Jones.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting at the Palatine Hotel, Manchester. The following Paper will be read: "Blackpool Electricity Works," by J. Hesketh.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Meeting at the Westminster Palace Hotel. Paper to be read and discussed: "The Construction and Working of Electro-motors," by A. H. Dykes.

ROYAL INSTITUTION.

9 p.m. Evening discourse on "Fortuitous Variation in Animals," by Prof. W. F. R. Weldon, F.R.S.

SATURDAY, February 10th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
- VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
- VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 8s. 6d. net, post free, 9s., abroad, 9s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price : Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; and Mr. Alexander Siemens have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

BELT-DRIVING *v.* DIRECT-DRIVING, AND OTHER CONTROVERSIES.

The rivalry between alternate currents and continuous will not cease for many a year; and it is commonly supposed that it will only be diminished when experience has proved that, other things being equal, districts exceeding a certain size should take advantage of the economies of the former, while smaller areas may enjoy the conveniences of the latter. But what irony and paradox is there in this use of the words "equal" and "certain"! As long as the glowing filament or arc carbon are used as sources of light, the battle will continue, and is likely to be settled as far as electric lighting is concerned, only after these sources of light have been superseded. For transmission of power no such distant end as this seems possible. American engineers of a mathematical turn of mind are at present engaged in hot discussion of the saving of copper in di-phase-three-wire and in tri-phase-Y or tri-phase-Δ systems, while the representative of electrical engineering in this country has recently suggested that continuous currents are better than all, even on a Niagara scale. The fight here is between an old, simple, and well understood, but fully developed system, and a new complicated, rather obscure principle which has hardly emerged from the experimental stage. Little or nothing remains to be calculated in

Digitized by Google

direct-current work; dynamos and motors are well-nigh perfect; insulation that has already been proved has only to be extended. But the fascination of multiphase systems, to say nothing of wide room for reduction of cost as well as of losses in ordinary transformers and alternators, will for many years attract enthusiasts and inspire engineers.

There seems to be no *à priori* reasons why electrical engineers should be of a combative disposition, but it is evident that they have many a tilting ground, and are generally ready to enter the lists on "direct *v.* alternating," "tube boiler *v.* shell," "rope or belt-driving *v.* direct-driving," and there are probably enough electrical engineers for a joust on "electromagnetic *v.* electrostatic voltmeters." Civil engineers on "concrete *v.* masonry" behave quite mildly in comparison, and such is the amiability of mechanical engineers that no topic for furious controversies suggests itself. Curiously enough, it is left for electrical engineers to dispute about two of the matters which we have instanced, matters on which only those electrical engineers who are at the same time mechanical engineers have any real arguments to offer. One of these, "rope or belt-driving *v.* direct-driving," is a subject admitting of no compromise. It is all very well to fix on a mile radius or a mile diameter as the limits of a continuous-current district of supply, and 500 volts as the point beyond which electrostatic voltmeters should be used; no such line divides dynamo driving into two portions. Belt-driving, for we will not discuss ropes *v.* belts, would be out of the question with steam turbines, but by no other means could such enormous speeds be approached, unless by belts. Nothing but positive inability to run without knocking at high speeds can be the unacknowledged excuse for such slow running as to make the cost of the dynamo a serious question. Nor does the actual scale impose any restriction on one system or the other; neither for a very large nor for a very small plant is there any special advantage in either mode. The disadvantage of direct-driving, due to the increased cost of a slow-speed dynamo, practically disappears in the large machines used in supply stations.

The adoption of direct-driven dynamos by the Admiralty has given a great impetus to fast-running engines, though it has not exercised, perhaps, so wide-spread and beneficial an influence as it has on dynamos. Had there been as many first-rate high-speed engines as there are first-rate contiuous-current dynamos, prejudice against direct driving might have been less. Direct-driving in Germany and elsewhere has led to the building of dynamos which are a standing wonder to English makers. The cost, the expanse of commutator, and the size and weight of these machines remain to us a marvel. It is probable that engines will be built to run faster, and that the output of these huge machines will be proportionately increased. The question of belt-driving *v.* direct-driving seems to resolve itself into cost of floor-space, wear and tear (including breakdowns), and cost of fuel. Experiences such as those recorded by Mr. Hesketh at Blackpool are, fortunately, rare, and the skill which they seem to engender, as is evinced by the short duration of the stoppages, is simply a waste of dexterity. Many engineers are almost unaware of the evils of belt-driving until they meet with a rope-driving enthusiast, and none know the troubles of rope-driving until they have had a few years' experience with it. Direct-driving men, many of whom know neither how to take care of a belt nor to splice a rope, are unaware of any evils at all. But this by no means settles the point. Belts and ropes admittedly enjoy shorter lives than the engines, and the increased wear and tear of the engines, if any, cannot be estimated for years. Where floor-space is a consideration it is to be observed that rope-driving requires from four to five times greater space than direct-driving; and even when jockey pulleys are used, as at Manchester, twice the floor-space is needed.

The coal bill is, as we have before observed, a smaller item in the cost of production than at one time seemed probable; but none the less, the coal bill measures the size of the plant, of the station, and of the staff, and its ratio to the output generally seems to measure the success of the system. For the present purpose we may consider steam consumption alone, and here, unfortunately, we have figures on one side only. Unrivalled as are the arrangements for measuring steam consumption at Thames Ditton, other engine-builders need not hesitate to provide a less perfect equipment only because there might be some doubt about the accuracy of the third figures in their results. We should be content with a ± 1 in the second figure rather than have, as at present, practically no figures at all. Rather because it is nobody's business to conduct steam trials than for want of time or opportunity, engineers of belt or rope-driven electric supply stations seem to have made no attempt to make test runs, and few engine-builders, beyond the mere giving of a so-called guarantee, ever say a word about steam consumption. It is true that the coal consumption at the generating station of the City and South London Railway, as given in their last accounts, works out at about 0·7d. per unit generated; but the load, though maintained all day, is so unsteady that this figure cannot carry much weight. The steam consumption per indicated horse-power has been carefully measured on many different kinds of engine, but the driving of dynamos affords such unparalleled opportunity for measuring the actual power delivered with the greatest exactness, that it is by such tests that the efficiency of slow-speed belt-driving can alone be compared with direct driving. In the absence of figures relating to the former system, we cannot attempt to come to any conclusion. Such figures are among the many might-have-beens of great exhibitions, and we can only wait until some non-direct-driving engine maker has some well-authenticated tests to publish. Meanwhile, we give in our correspondence columns, not only the latest but, we believe, the best figures that have ever been announced, namely, a combined efficiency of 88·04 per cent. for a Siemens-Willans 300-H.P. plant.

ELECTROSTATIC VOLTMETERS.

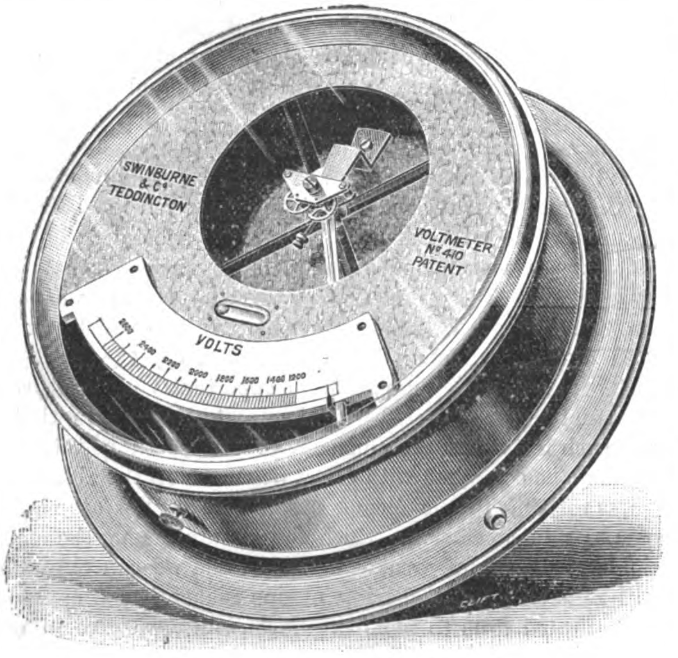
After much trouble and money had been spent by instrument makers on the perfecting of the Cardew voltmeter, magnetic voltmeters were made, rivalling the Cardew in accuracy, and, like that instrument, could be left on the circuit for any length of time. When alternating currents became fashionable, the Cardew voltmeter came to the front again, but high pressures could not be measured without the use of resistances, or of small transformers. The former expedient was wasteful, and the latter for several reasons untrustworthy. Demand, however, was soon followed by the supply of excellent magnetic voltmeters, slight modifications of the direct-current instruments, and thoroughly suitable for their work. There was but little difficulty in making voltmeters which would read correctly at any given frequency, and although this could always be specified at the time of ordering, it prevented the stocking of such instruments by dealers. For high pressures external resistances are still necessary, but much less current is required than for a Cardew voltmeter.

Electrostatic voltmeters consume no current, and are independent of frequency, but the directive force is small, and where large bare metallic surfaces are employed precautions must be taken against short-circuiting by sparking. The

Digitized by Google

Kelvin, the Ayrton-Mather, and the Swinburne electrostatic voltmeters stand foremost among the various instruments of this class, and the first two kinds employ the multicellular principle for measuring comparatively low pressures, and the last is intended only for use on primary circuits of over one thousand volts, although one-third of this can be measured if required. We have recently received a few particulars of the Ayrton-Mather and of the Swinburne instruments. The former of these has been fully described in these columns,* and, as we stated in a Trade Note last week, has been made by Mr. R. W. Paul. We understand that they are now being also made by Messrs. Elliott Bros., who are introducing a reflecting instrument for use either with a lamp and scale or with a telescope.

The Swinburne electrostatic voltmeter was described in *The Electrician* in connection with the experiments by Dr. Fleming on various transformers. An early form of this instrument was used in this investigation. It consists essentially of a quadrant electrometer with quadrant boxes, as shown in the illustration, and flat aluminium vanes. A long series of



The Swinburne Electrostatic Voltmeter.

experiments have been carried out with the object of converting a delicate laboratory instrument into a substantial voltmeter, fit for use on switchboards. The vanes had to be made without solder, as it was necessary to avoid softening the aluminium, and the surface has been punched with many holes to decrease its mass, thus allowing the instrument to be handled without fear of bending the vanes. The vanes are shaped so as to give a scale evenly divided near the standard pressure, for which the voltmeter is intended. The contour of the vanes determine this, and although, of course, all the middle part could not be removed, the vane punched with holes acts practically as a grating or continuous sheet. The directive force being small, great care has been taken in the mounting. Jewelled bearings have been avoided, owing to the delicacy and weakness of the fine pivots which must be used with them. Friction wheels, as shown in the illustration, are employed, and the spindle and other parts of the movement are strongly made. The coaxial, or cylindrical system, has been tried by Messrs. Swinburne and Co., but was abandoned by them in favour of the present design. The instrument is fitted with double-pole fuses, suitable for high pressures, the insulation resistance is very high, and the experience of the makers with the experimental use of more than 100,000 volts, and of voltmeters for measuring such pressures, has been employed in preventing sparking between the different parts of this voltmeter.

* *The Electrician*, Vol. XXXI., p. 151.

NOTES OF A TRIP TO THE UNITED STATES AND TO CHICAGO, 1893.*

BY W. H. PREECE, C.B., F.R.S., PAST-PRESIDENT.

In 1877, together with Mr. H. C. Fischer, I made an official and thorough inspection of the telegraphic system of the United States and Canada, and the lessons of that journey were reported to this Institution on February 13, 1878. The results of that trip were the introduction of the telephone, the practical application of quadruplex working, the adoption of sound reading in our telegraph offices, the disappearance of the Morse recorder, and the more general assimilation of the methods of working in the two countries. In 1884, as a member of the British Association, I again visited Canada, and made another tour through the States, reporting my observations to the Institution on December 11, 1884. The chief result of this second trip was the introduction of the multiplex system of working of Mr. Delany, now so much in use amongst us, and doing splendid service with many of our chief towns; hexode working, six messages in any direction, are simultaneously transmitted between London, Brighton, Bristol, Birmingham, and other commercial centres. The telephone was found fully developed, and firmly rooted as an invaluable aid in domestic and business requirements. The electric light was making great advances, especially as the illuminant of public streets and ways, to the great advantage and safety of the public, but electric railways and the transmission of power were only just looming in the air in an extremely tentative and experimental stage. Now I am able to report another tale of a ten weeks' trip taken in August and September last over much the same ground, but with two *pièces de résistance* thrown in—a visit to the great "World's Fair," and the holding of an Electrical Congress at Chicago.

I.—Telegraphs.

The telegraphic system in the United States is in the hands of two great private telegraph companies, the Western Union Telegraph Company and the Postal Telegraph Company.

The Western Union Telegraph Company, which is by far the larger of the two, is a gigantic undertaking. It is a congerie of at least 500 other companies which have been purchased, absorbed, or amalgamated from time to time; and it is also closely connected with virtually all the railways in the States. This connection with the railway companies gives it a very prominent and commanding position over its rival. In order to show the progress made since 1884, and the present condition of the business, I give the following table:—

Particulars.	1884.	1893.	Great Britain, 1892.
Miles of poles and cables	145,037	189,936	33,689
Miles of wire	450,571	769,201	207,231
Offices	13,761	21,078	8,537
Messages	42,076,226	66,591,858	72,302,556
Capital	$80,000,000	$123,000,000	£10,130,820
Receipts	$19,632,940	$24,978,442	£2,486,791
Expenses	$13,022,504	$17,482,405	£2,470,839

The Postal Telegraph Company is a very much smaller concern. It has virtually come into existence since my previous visit, for when I was last in the States it had just commenced its operations, and it only possessed 1,500 miles of line and 4,260 miles of wires. It is a Company which has been promoted, not so much to attack the Western Union Company, as was the case with all previous competing lines, but to establish a collecting company for the cable business which is in the hands of the Commercial Cable Company. The present position of the Postal Telegraph Company is as follows:—

Miles of line	15,997
Miles of wire..	99,664
Offices..	2,664*
Messages..	9,335,291

* Of this number, 860, or nearly one-third, are situated out of the States, in Canada and elsewhere.

The enterprise in telegraph work is evident at once on landing in New York. Every passenger on landing at the dock stage is approached by a messenger from one or both Companies, soliciting messages; and on all stages, except that of the Cunard Company, one or other of the telegraph companies has succeeded in establishing an office. The business done at these offices is very great, as, when facilities are thus given to passengers to send messages, nearly everyone wires home his or her safe arrival. This enterprise is evident everywhere. The blue and white sign of the Western Union Company, which is extremely prominent, is found in every hotel, at all railway stations, and in large cities, and is as abundant as the Post Office sign is in England. At Long Branch,

* Paper read before the Institution of Electrical Engineers, January 25th.

Digitized by Google

the Brighton of New York, where I spent two or three very pleasant days, there were no less than 19 offices belonging to the Western Union Company, and all paying. There were 20 offices in the World's Fair alone, and 70 hotels in Chicago have Western Union offices in them.

Competition is intense, but there is no war of rates. A general tariff has been agreed upon, and the only rivalry that exists is in the collection and transaction of business. Dividend-earning being the chief end aimed at, only paying commercial stations are properly served. Social and domestic telegraphy is practically ignored, and sparsely populated districts are very inadequately provided for. Hence in the United States telegraph business is neither so general nor so cheap as it is with us. The average price received per message is 15¾d., as against 7·7d. earned by us. On the other hand, however, it must be remembered that their mean distance is far in excess of ours.

Construction of Lines.

I inspected considerable lengths of the line work constructed by each company, and drove over many miles of a new road line passing through Connecticut. In this direction American electrical engineers have been very much behind us. They have not built their lines so solidly, nor have they followed true engineering principles in the same way that we have. As a rule, their lines are extremely irregular, being badly constructed with poles that we in England would not look at. But recently, owing to the difficulty in finding fresh routes, the growth of the number of the wires, and to the absolute necessity for accuracy of workmanship for securing silence on telephone lines, great improvemenes have been made, and some of the trunk lines put up by the telephone companies, and the new trunk line put up by the Postal Telegraph Company, will compare very favourably with our best modes of construction.

The telephone line to which I have alluded above consists of 16 arms, each carrying 10 wires, or 160 wires in all ; the poles are 60ft. high, and are placed 100ft. apart. The arms are of pine, and their scantling is 3¼in. by 4¼in., and they are 10ft. long. Owing to the use of wooden pins they are bored with holes 1¼in. in diameter. This weakens the arm, and I observed two instances where arms were broken. A 6ft. arm bored for four insulators costs 15 cents, which is cheap compared with the price we pay. But they are undoubtedly weak, and not to be compared with the oak arms that we use. As a rule the poles number 40 to the mile. They are generally of cedar, but sometimes of chestnut. The cedar poles come from Canada and Michigan. Each 25ft. cedar pole costs $2.25, and is said to last 15 years without preparation. The chestnut pole is a little cheaper, and it lasts only 10 years. It is extremely irregular in shape.

American engineers do not adopt the same plan that we adopt in the erection of arms. They are fixed any way, but generally on the modern lines they alternate on each side of the pole. This is done under the impression that it adds strength to the line. I do not know why it should. (We invariably fix the arms on that side of the pole facing London.) Every fifth pole is earthed as a protection against lightning. (We earth-wire every pole.) Stays are very little used indeed, but on new lines they have longitudinal stays in the direction of the wires, one end being fixed at the foot of one pole, and the other end at the top of the next pole. These are called "head guys," and are frequent. Iron poles are used only for electric railways. These are very substantial, and look very well. They are made in three sections of simple iron tubes, either 6in., 5in. and 4in., or 5in., 4in., and 3in. in diameter respectively. Pole roofs are not used as with us, but the poles are tapered off to throw off the rain.

Neither the Western Union nor the Postal Telegraph Company adopt any system for preparing their timber to resist decay. My attention had been called to a system of artificial seasoning called "wood vulcanising," and it was reported that this system had been adopted by the Western Union Company. I found this was not true. The Western Union Company had experimentally tried the system on some wooden troughing, employed for the protection of their pneumatic tubes underground ; but the process was so expensive, and the advantages so doubtful, that they do not apply it to their poles or their arms.

Copper wire is very much used on telegraph and telephone lines. I saw in the Exhibition at Chicago a form of wire called "tempered copper." This is said to be extremely strong and hard, but it is evidently an alloy of copper, for its resistance is high. I was surprised to find that a compound wire 1·7 ohms resistance per mile, put up by the Postal Telegraph Company in 1883, is still in use, and working well. Our experience of the durability of this wire was disastrous.

Underground Work.

Underground work was scarcely started in the States in 1884, but now, owing to peremptory legislation on the part of the municipalities, it has made very rapid progress. Underground work in the cities of the States has become general, with great advantage to the public and also, as they have come to acknowledge, to the companies themselves. The only exception to this rule that I heard of was at Boston, where complaint was made that their underground system had been much disturbed by "wash-outs." These "wash-outs" are freshets, or great floods, tearing up the line and carrying away the pipes and wires. The system of underground work adopted by the telegraph companies in America does not differ much from that adopted by us, excepting that they do not use gutta-percha, owing to its high price. They are using very largely a cable similar to the Fowler-Waring cables, and also kerite-covered wire. Kerite is a form of vulcanised india-rubber.

Offices.

Not much change has been effected in the mode of fitting up offices. Glass of the best quality is used very much indeed: doors, partitions, boxes for the collection of messages, are all made of thick glass. This looks very clean and nice, and is certainly effective. There is an extremely efficient mode of collecting and distributing messages in the Western Union offices at New York and Chicago. Endless cords are kept in motion by means of small electric motors, and these cords transport small metal carriers somewhat similar to those we use in our pneumatic tubes. Before leaving New York I saw an improvement on this by which messages can be picked up as by the finger and thumb from the desk in front of each operater. They also have in use a system by which messages, envelopes, slips, &c,, are conveyed by broad continuous leather belts, 8in. wide, kept in rapid motion by motors, and upon which the messages, &c., are laid, and carried to the point desired.

Each company has adopted a uniform and pretty-looking box for its office in the hotels. American hotels differ from ours in this: The hall of an hotel is usually open to the public, and no hotel that I entered was unfurnished with a telegraph office. I have mentioned that there were 70 hotel offices in Chicago. In fact, hotel proprietors court the presence of a telegraph office. Space is usually accorded free, and board is also provided for the operator. In some places, like the "Palmer House" Hotel at Chicago, which is a great business centre, a very high rent is demanded ; but, generally speaking, no rent at all is paid. At the hotel I stayed at in Chicago—"The Lexington"—each company had an office in the hall ; the rivalry that exists between the two companies taking the form of each striving to work with the louder sounder. The louder was that of the Postal Telegraph Company, and when I asked the operator why he allowed his instrument to make such a row, he replied, "We must beat the Western Union Company anyhow."

At Fort Sheridan, a military station about 20 miles away from Chicago, the Western Union Company opened an office, although the place contained only 1,000 soldiers. The office was worked by the soldiers, and I was assured by the Company that they found it pay well.

The common system in the States is to tile the floors of their telegraph galleries, and not to board them. Fireproof channels, or conduits fitted with slate tops, are arranged about the office for the distributions of the wires. Lockers for coats and hats are roomy and well made, and ample in the supply. At Chicago they are of open ironwork, very neatly made, 6ft. 6in. high, and 28in. by 8in. in sectional area. Four men, each of whom is supplied with a key, use such a locker. Great advantage is said to arise from the use of these open lockers in wet weather, and they are worth our own consideration. The use of bicycles for messengers is very prevalent in the States.

Batteries at all the principal offices in the United States are gradually disappearing. The current for working the circuits is being supplied from dynamos, or from the electric lighting mains. In New York from 30,000 to 40,000 cells have been replaced by dynamos. At Boston 10,000 cells, which cost probably £4,000 per annum to maintain, have been replaced by current derived from the electric light mains at a cost of £600 a year. It must be remembered that the American telegraph circuits are worked entirely on the closed-circuit system. They use immense cells, and their cost of maintenance is excessive. We cannot compare their system with ours in this respect, for we use open circuits ; and the maintenance of our batteries is certainly, cell for cell, not more than one-fourth or one-fifth that of the United States form of battery. In New York the Western Union Company have a special plant of 51 small dynamos. In Chicago they have 46. The Postal Telegraph Company in New York are also using dynamos, and in their new station which is being built they are supplying what they believe to be an improvement on the system adopted by the Western Union Company.

We have shown in England that the use of dynamos, owing to the variation current, is not suitable for high-speed working, and I much prefer the plan that we have adopted with so much success in working our Continental circuits—namely, the use of accumulators. Accumulators have an immense advantage over dynamos ; they store up energy, so that in the event of any accident or breakdown of machinery the accumulator maintains

Digitized by Google

the circuits working. The accumulator is not in motion. There is no machinery to fail or to break. There is nothing to stop, and little to get out of order. But the chief advantage of the accumulator is the absolute steadiness of its voltage There is also economy in capital expenditure, and I am quite convinced that the Western Union Company in New York would have effected considerable economy if they had used accumulators charged by the electric lighting plant, instead of supplying the elaborate series of engines and dynamos now working their circuits direct.

At Boston and other stations a very well-made and well-designed motor-dynamo is supplied by Messrs. Crocker-Wheeler. They are primarily motors worked on the 110-volt electric lighting service, driving a small dynamo, and they transform this down to a voltage which will charge any number of cells required. This system is in use by all the telephone companies, and, as I will point out when speaking of telephones, the service is much improved by the use of accumulators thus charged.

Apparatus.

I observed little or no progress in the form of apparatus used. In neither company has there been any advance made on the systems in use in 1884. Duplex and quadruplex working are principally relied upon, while on the long-distance lines Wheatstone working is gaining ground, and being much more used. The only novel mode of working that was brought to my attention was a system of working cables automatically. This system has been threshed out by Mr. Wilmot at Waterville, and adopted by the Commercial Cable Company, but it has been very much improved upon by Mr. Delany, the inventor of our multiplex system.

Typewriters have become quite common. The rule is for an operator to have his own machine. The Postal Telegraph Company use this system more largely than the Western Union Company. The latter company employ it invariably for their Wheatstone and other news circuits, but the Postal Telegraph Company use it very largely on all circuits, and I watched many operators taking off messages by ear and typewriting them at the same time, and in all cases the typewriting machine held the sounder well in hand as regards speed.

The working of the Wheatstone system between New York and Chicago is admirable. The grand total of messages handled in one day on this circuit is certainly astonishing. 4,211 messages have been passed between these two places on one circuit in a day —a number that we can scarcely hope to rival. The reason for this is not the greater speed at which the apparatus is worked— for the speed is less than ours—but to the fact that the business day in the United States extends over a much greater number of hours than with us. The business day in New York commences three hours before that in San Francisco, and the business day in San Francisco extends for three hours beyond the business day in New York. Hence the business day, which in England scarcely extends telegraphically to four hours, in the United States extends probably to twelve hours. Thus the number of messages handled is much greater per day than with us.

The advantage of Wheatstone working to the Company was illustrated while I was there. On August 29th a cyclone in the eastern part of the States prostrated the poles and wires for miles throughout half-a-dozen States. Three Wheatstone circuits were maintained working—and working badly—between Chicago and New York by means of repeaters at Buffalo and Pittsburg, but on these three circuits 8,693 messages were handled. This was the only means of telegraphic communication between the Eastern and Western States. Curiously enough, the new and strong long-distance telephone line was not broken down. On August 18th, while I was there, I took down as having been sent between 8 a.m. and 5:30 p.m.—forwarded, 1,272 ; received, 1,889. This work was handled on two circuits, with an average speed of 190 words per minute.

The Wheatstone system in the States is much more extensive in the West than in the East. It is giving such good service that it will probably receive considerable additions this year. It must be remembered that between Chicago and San Francisco we are dealing with a distance of 2,500 miles, and on this circuit they were working when I was there at the rate of 110 words per minute.

I observed a very high rate of working on some of the quadruplex circuits. I took down these figures at Boston :—

Forwarded	686
Received	521

This was an ordinary day's work. On another circuit, between 8:30 a.m. and 11:30 a.m., in Buffalo, the numbers were :—

Forwarded	126
Received	140

on one side of the quadruplex only.

I noticed at the Chicago Exhibition, in the French exhibit, a new adaptation of multiplex working by M. Mercadier, who showed in operation twelve working sides. But the working, although interesting, was poor. The reading was done by telephone, and each branch was selected by the sounding of a particular note. The apparatus is not yet in anything approaching a practical stage, but for short lines something may some day come out of it.

Pneumatic Tubes.

The Western Union Company have not extended their system of pneumatic tubes greatly since may last visit. The Postal Telegraph Company are about to use pneumatic tubes for the distribution of their internal work in their new building on a plan somewhat similar to that which we use at our central station.

The only novelty in pneumatic tubes that I saw was that on trial between the Post Office at Philadelphia and a sub-office in Chestnut-street. This is a line of two pipes 6¼in. diameter and 5,792ft. in total length—that is, a distance between the two offices of 2,896ft. The carriers are metal cylinders whose inside dimensions are 16in. long and 5¼in. in diameter. They weigh 6lb. each, and carry 120 letters. The carrying capacity of the line is said to be 180,000 letters per hour, but I think this is exaggerrated ; the time taken by a carrier in transit is 55 seconds, and the air pressure is maintained at 7lb. per sq. in. The line has been working since February 17th, and it has been used for the transmission of letters, the whole service to this particular sub-office being done through the pipe. The pipe is continuous, and a current of air is constantly flowing through it. Twenty-five horse-power is absorbed in maintaining this current at the pressure required, and the carriers are said to move at the rate of 40 miles an hour. Twenty-five carriers are in use. Unfortunately, while I was there the tube was out of use, for the boilers had broken down. These boilers belong to the Post Office Administration, and were not under the control of the contractors who are carrying out the experiment. It is merely an experiment, but it is an experiment that has been carried out in a very practical manner, and they are threshing out a question that may be of importance. They find that the tube used is too small for their purposes, and they are going to use in future an 8-inch tube.

Distribution of Time.

A feature of considerable interest and novelty is the distribution of time by the Western Union Company. Correct time is received every day at noon from Washington. The time current lasts one second. Time balls are dropped at Boston, Newport, Woods' Holl, New York, Philadelphia, Baltimore, Washington, Fortress Monroe, Savannah, New Orleans, and Havanna. This current is also distributed by the Western Union Company to subscribers in the principal centres. In New York there are 1,100 subscribers, in Chicago there are 1,837, while in the whole of the Western District of the Company there are 7,963 subscribers. Each of these subscribers has a special wire upon which the time currents are sent from a master or a controlling clock. The Western Union Company also furnish synchronous self-winding clocks to the subscribers, which are controlled and regulated daily by these time-signal currents. They are wound automatically every hour. The rates for this service are not excessive. Each subscriber is charged $2¼ per month, while large buildings using five or more clocks get the time signal supplied at $1¼ per clock per month. The standard time adopted in 1883 is virtually Greenwich time. It is divided into four sections. The following table will show how far these differ from Greenwich meantime and from each other :—

W. Long.	Centre.	Actual time.	Name adopted.
0°	Navigators' time (Greenwich)	Noon.	Greenwich time.
75°	Washington Meridian	7 a.m.	Eastern time.
90°	Chicago Meridian	6 a.m.	Central time.
105	Denver Meridian	5 a.m.	Mountain time.
120°	San Francisco	4 a.m.	Pacific time.

Thus the minutes and the seconds are the same as with us. There is no necessity to alter one's watch.

Hefner von Alteneck proposes to place clocks in the circuit of an ordinary glow lamp, and to wind and control them by a slight change in the current made at the central station once a day. It is surprising what can be done by electricity when it is laid on in a house and served from a central station. Von Alteneck's system was exhibited at the World's Fair.

Conclusions.

It is quite impossible to inspect the telegraph system of the United States and compare it with our own system without drawing comparisons between the way in which the work is done in the two countries. The result of my previous visit was to confirm my view that we do our work better in England than they do in the States. Our apparatus is better, our speed is higher. Messages are handled with greater reliability. A message can be sent and its reply received with certainty in an hour in England. I fancy such rapidity would astonish the users of the telegraph in the States, except those in such busy centres as New York and Chicago, and

Digitized by Google

generally the speculative branches of the community. The domestic telegram scarcely seems to have reached the United States, and this is owing, probably, to the fact that the districts of private residences, the small towns, and the villages do not possess telegraph offices, unless they are supplied by the railway company at the railway station, or by the Western Union Company, who do the work for the railway company.

I fail to see any superiority in the manipulation skill of American operators. They certainly have not made the same advance in technical education that we have, and altogether it may be said that the management of the telegraphs in the States in the hands of the private enterprise does not compare favourably with the management of the telegraphs by the State at home. At the same time, it must not be assumed, because the Government have advantageously taken the telegraphs in hand at home, that such a process would be possible in the States. In my opinion it would be absolutely impossible. The Civil Service of the States is in a very chaotic condition. The principal appointments are four-years appointments only, and are filled politically. The principal postmasters come in and go out with each new President. We in England scarcely consider that a postmaster is fit to be a postmaster until he has had many years' experience of the working of the Post Office system. In the States a man is made a postmaster because he has been a political supporter. At one or two offices I found the new Post Office officials absolutely ignorant of simple facts they ought to have had at their fingers' ends. A business like that of telephones or telegraphs can only be conducted properly by those who possess a considerable amount of enterprise, and who look primarily to the necessities of the community. The reason why our post offices and our telegraph offices at home work so well is becsuse the public exercises such a useful and such a determined supervision over the work. The free opening of the Press to complaints; the readiness with which members of the House of Commons ask questions—though at times, perhaps, irritating and vexatious—are undoubtedly good for the service, for they keep us all alive. Such a state of affairs is impossible in the States.

The Govenmment of the United States must first reform its Civil Service, and when it gets officials into the service whose tenure of office is secure, and whose zeal is as unquestioned as it is in England, then there will be some chance of their Government acquiring the telegraphs; but under existing circumstances the acquisition of the telegraphs by the Government of the United States would amount virtually to the deterioration of the service. The commercial management is at present, as I have pointed out, characterised by great energy. I do not, however, acknowledge that they show greater energy than we do in England. Competition may make it more conspicuous, but it is not more reaching. Our speculative business, stocks and racing, is done as well as theirs. The management at home is characterised in all particulars with similar energy to that which I observed in the States; and I come back without any views or wrinkles which I think could be impressed with advantage on the commercial or technical management of our system at home, unless it be the encouragement of offices in hotels, for it is found everywhere that a telegraph office at one's door prompts the desire or want to telegraph.

The capital of the Western Union Telegraph Company was in 1877 $22,000,000; that of the British Post Office was £10,000,000. The capital of the former is now $123,000,000, while that of the latter remains virtually the same. Scarcely a single vestige of the old telegraph companies' systems purchased by the State in this country now remains. Whence, therefore, this splendid system of cables, underground lines, and new pole lines in this country, spreading everywhere, and transacting an annual business of £2,500,000, instead of the £600,000 handed over to us? It has all been paid for out of revenue! The Government keeps no capital account.

How do we do our work? The proof of the pudding is in the eating thereof. The criterion of telegraph working is rapid despatch. "Time is our only competitor," said Dr. Norvin Green. The time occupied in its transit from the hands of the sender to those of the receiver is the pudding. The whole of the messages arriving in Newcastle on the morning of January 20th were examined and analysed. The mean time of transit from all parts of the United Kingdom averaged 7·8min. A similar examination at Glasgow on January 15th gave a mean result of 8·7min. This cannot be beaten, and it certainly will not be believed. The late Mr. Patey was once asked why express telegraph service at higher rates was not introduced in England. His answer was, "All our messages are express already."

II.—Telephones.

The business of telephony in the United States has made gigantic strides since I visited that country in 1884. The following table will show the position of the industry then and now.

It will be seen that there is a very small increase in the number of exchanges opened. This is owing to the fact that hitherto there has been a tendency to centralise the exchange work; and while many exchanges have been abandoned, the small increase is due to the fact that many new exchanges have been opened.

It will also be noticed that in the States they have gone in very largely for underground work. This has been forced upon them by municipal action. In addition to this, the companies themselves have been compelled by the indifferent working of their systems to fall back upon the metallic circuit, and now there are 23,053 metallic circuits in use. In New York 62 per cent. of the circuits are metallic, in Buffalo 77·84 per cent., in Boston over 50 per cent., in Chicago 20 per cent., and in Brooklyn 60 per cent.

——	1884.	1893 (January 1st).
Miles of wire	115.255	440.793
Miles of underground wire	Nil	91.463
Telephones in use	325.574	552.720*
Telephone subscribers	123,625	232.140
Number of connections between subscribers and exchange	215 millions	600 millions (est.)
Telephone exchanges	1.325	1.351
Staff employed	4,762	9,970

* This is the total number of transmitters and receivers. According to our system of reckoning, where the two together are considered as one instrument, the number given should be divided by two. Thus, for comparative purposes, it may be said that the United States has 276.360 telephones in use.

The business of telephony in the United States is a gigantic monopoly in the hands of the American Bell Telephone Company, whose headquarters are at Boston. This company owns more than one-half the stock in every telephone company in the States. It holds itself the whole of the stock of what is commonly known as the Long-Distance Telephone Company, but which is really entitled the American Telephone and Telegraph Company, and thus by having control of the stock in every company it maintains the power and monopoly. The advantage of this monopoly is the establishment of a uniformity of working and practice that is highly and extremely beneficial. The form of apparatus used, the mode of working, the details of construction, and all the methods in use are dictated from Boston. The result is little or no friction; and while each independent company is self-managed and self-contained, nevertheless it is subservient to the direction and control of headquarters at Boston. There is no divided responsibility in the United States. Every town has but one system. The result is that the service is thoroughly and perfectly performed. In those parts of the country where metallic circuits have not yet been adopted there may be defects in working, but these are rapidly being removed, for the benefit derived from metallic-circuit working is being felt everywhere in the United States.

Exchanges.

The modes of working may be divided into three classes—(*a*) That dealing with local subscribers alone working upon a single exchange; (*b*) That dealing with trunk working between exchanges in one town or district: and (*c*) That dealing with long-distance speaking, such as that between New York and Boston, New York and Philadelphia, New York and Chicago.

I visited three exchanges at Chicago, one at Buffalo, one at Boston, and three in New York, and I looked very thoroughly into the working of each system. While I did not think that any of their local working is done any better than, if as well as, the local working on our own exchange at Newcastle-on-Tyne, there is no doubt that in their trunk working, both for inter-exchange communication and for long-distance working, they are far ahead of us in England.

The prevailing switch in the United States is the multiple board, made by the Western Electric Manufacturing Company. The largest board in the world is one which I carefully examined at the Cortlandt-street Central Exchange in New York. It has a capacity for 6,000 subscribers; it is 263ft. long, and is divided into 40 sections. One operator handles 60 subscribers. There are 260,000 holes, or "jacks," as they are called in the States; while in fitting up this switch 780,000 soldered joints were made.

It is found in the States that multiple boards can become too large, too unwieldy, and they introduce troubles of their own that have to be remedied. These defects are aggravated when there are several exchanges in the same city. In Chicago Main Exchange 25 per cent. of the business, in Harrison-street Exchange 94 per cent., is trunked out. The average trunking is 50 per cent. A multiple board is, therefore, useful for only 50 per cent. of the work done. It should be explained here that the term "trunk" is adopted in America to indicate connections effected between one exchange and another within the same area. Connections between town and town are designated "long-distance" connections. The tendency is to depart from the principle of the multiple switch; and an extremely interesting

Digitized by Google

experiment is being carried out simultaneously in Chicago, Buffalo, and New York to determine the merits of a new system of working called the "divided" board. The divided board means this:—There are two boards, the one called the *answering* board, and the other the *connecting* board. The answering board contains the indicators and trunks, including those to the connecting board, and all local connections are treated as trunks through the connecting board. Thus, while each operator at the answering board attends to and answers only her 60 subscribers, and is able still to control all the trunk wires, the local spring jacks are duplicated on the connecting board, which may contain one, two, or three complete sections, as the case may be, and are attended to by separate operators. All the business is thus trunked. The result is that the service performed for the subscribers for local connections is slightly retarded. On the other hand, the work done on the trunks is equally expedited. If 50 per cent. of the work done in the Central Exchange is trunk work, it is argued that, if subscribers find that one-half of their work is expedited and the other retarded, the expediting of the more important part will compensate for the retardation of the less important, and the general result will be beneficial. The chief merit of the divided board is that it reduces the "jacks," as the switch-holes are called. Seven sections of board with 42,000 jacks would replace 40 sections with 240,000 jacks in an exchange of 6,000 subscribers. I find opinion, however, divided upon this question; but the view is very general that when the multiple switchboard exceeds a capacity of 2,500 subscribers it certainly introduces disadvantages and defects which must in some way or other be remedied.

Trunk Working.

The trunk working is wonderfully well done. In the first place, the connections between the different exchanges are very numerous. In the Central Exchange at Chicago there are 344 outgoing and 325 incoming trunks. There are 11 exchanges, and these exchanges are located as nearly as possible in the centres of the districts which they are designed to serve. The business of these offices, however, is by no means self-contained, and a very great amount of their work is in handling calls from subscribers in one exchange to subscribers in another. These are now handled by means of 954 trunk circuits extending between the various offices, the total number outgoing from each office being as follows:—

Main	344	Oakland	68
North	34	Lake View	26
South	77	Harrison	59
West	74	Wentworth	19
Canal	63	World's Fair	80
Yards	61		

In Boston, between their Central Station and Tremont Exchange—an exchange of 833 subscribers—there are 27 outgoing and 33 incoming trunks. The service between two exchanges is virtually a silent one. No question is asked, but instructions are given simply—"301 on North 273." This is spoken on a call circuit. The trunk operator—always a male—wears a headgear telephone, receives this instruction, and carries it out without a word being said, or a second lost. In some places the subscriber, if he wants a subscriber on another exchange, calls his own exchange as usual, and, on getting attention, says "Tremont." He is then placed in connection with the Tremont Exchange, and he himself asks for the number he wants. The former plan is, however, the more general one, and that which is preferred. There are always so many trunk wires available that the operator has rarely to say "Wires engaged," or "Busy," which is the common expression. I never saw one case of the kind myself. The hourly maximum number of trunk calls between Boston (Main) and Tremont Exchanges was—From Boston, 557; to Boston, 475. The former averaged 20½ per circuit. The latter averaged 14½ per circuit. The result is that in places like Chicago, where there are 11 exchanges, and New York, where there are 9 exchanges, the trunk working is done between them virtually as though the whole of the exchanges were centred in one big hall.

The long-distance work is done in the same way. Only metallic circuits are switched on to the long-distance lines. The incoming trunk wires end in plugs, the outgoing trunk wires end in "jacks," so that when an operator hears "351 on Chicago 3," he simply takes up 351 plug and puts in a Chicago jack without hesitation. If, however, all the Chicago jacks are busy—which he sees at once by the visual signal—he says, "Busy," and the caller has to wait his turn. In my experience this occurred but rarely. When the calls were heard, the connections were made as rapidly as possible for it to be done, or as rapidly as one could wish that it should be done. In New York the Long-Distance Company and the New York Telephone Company are in the same building. A complete section of the New York multiple board is in the long-distance switch-room, so that connections are made *direct* between the long-distance lines and the subscribers. Usually a section of the multiple board in the local exchange is allotted for long-distance trunk work to the long-distance office, which may be elsewhere. It is so arranged that when a subscriber talks on a long-distance line his own circuit is entirely cut out from the local operating switchboard. There are a great many public call offices open in every city. There are 535 in New York. They call them "public pay stations." People pay tolls, and they come in and speak to the exchanges and get their connections through.

Long-Distance Working.

The long-distance speaking in the States is very popular and very successful. The opening of the circuit between New York and Chicago—a distance of nearly 1,000 miles—was so successful that they immediately found it necessary to erect two more circuits. There are now, therefore, three circuits between these two places. I tested these circuits, and found the working remarkably good. It was difficult to say that it was better or worse than the working of our London-Paris line. The tariff for the long-distance work is based upon 1 cent per mile for five minutes' talk. The greatest distance that I found upon which speech was conducted was between Milwaukee and Portland, and between these places talking costs $11 (44s.) per five minutes.

Rate of Working.

I found that the customers dealt with by each operator varied very much in different towns. The following table will show this:

Town.	Customers for operator.	
	Local.	Long-distance trunk.
Theoretical	100	6
Chicago	66	6
Buffalo	100	—*
Boston	70	3
New York 18th-street	50	6
Brooklyn	66	10
New York, Cortlandt-street	60	—*

* I did not record the number in these two exchanges.

The daily calls per circuit also vary very much. The average per day over the whole country is 8·03. At Chicago on one exchange it reaches to as many as 24·3; the mean for the whole town in January was 13·6, while in July it was 12·3. At Buffalo the mean is 6. It is interesting to note that the number at Buffalo is just the same as it was when I visited that place in 1884. At Boston the average number then was 5; it is now 12·6. While this average of 12 or 13 calls per day is not an extraordinary one, it represents great extremes in the use of telephones, which bring about complications which are at times difficult to meet. There are in the main exchange at Chicago at the present time several hundred telephones which are used more than 100 times each day. Nearly all this business is handled between the hours of 9 a.m. and 5 p.m. During the busiest hours of the day these instruments are in use almost continually. When calls are made for them, therefore, the only reply is that they are busy. As an example of this excessive use, my attention was called to the case of the Waukesha Hygeia Mineral Springs Company, telephone No. 929 South. A complaint was made by one of their branch offices that they could not reach the main office, the line always being reported to be busy. A record was made of the calls handled on this telephone, and in one day it was found to be used a total of 449 times, there having been 18 originating calls and 431 calls received. In one hour the telephone was used 51 times. This is, perhaps, the busiest line of which there is a record. Telephones used by railway offices, wholesale houses of all kinds, hotels, and many other places, are apparently in use almost continuously in the busy hours of the day. Many such establishments have more than one telephone, some of them having as many as six.

The subscribers per exchange in the exchanges that I visited are as follows:—

Chicago .... 10,312, divided thus:—

Main	4,912	Oakland	655
South	1,037	Lake View	244
North	996	Wentworth	46
West	903	World's Fair	269
Canal	434	Harrison	424
Yards	392		

New York, Cortlandt-street	4,500
Boston, Central	3,545

The total subscribers in New York are 9,574, at Brooklyn 4,800, and at New Jersey 4,900, making a total for New York and district of 19,274.

Underground Work.

The statistics that I have given show how rapidly underground cables have come into use in the States. At the Chicago Central Exchange, 76 cables, each containing 100 wires, enter the building

Digitized by Google

and ascend up a shoot to the exchange room. The conductor used is smaller than that adopted by us. It is only No. 19 Brown and Sharpe gauge. It gives 47 ohms resistance per mile, and it has a capacity of 0·68 microfarads per mile. The insulation must be 500 megohms per mile at 60°F. All cables before being used are very carefully tested, not only to see that they comply with the specification as to conductivity, capacity, and insulation, but also for what is called "cross talk," by means of buzzers.

There are no less than 14,034 miles of underground wire in New York; 160 cables, each containing 100 wires, enter Cortland-street building—that is, 16,000 wires enters this exchange. In Boston 91 lead-covered cables enter—that is, 10,920 wires in all, for each cable carries 120 wires. The cables are made for 50, 60, or 100 pairs of wires. The 50-pair cables have a diameter of 1¾in., the 60 and 100-pair cables being 2in. and 2¼in. in diameter respectively. These cables are in all cases brought straight to distributing boards in a room alongside the switchboard room, and here they are brought to terminals in a way similar to that adopted by us, so that changes can rapidly be made. Subscribers' lines are so distributed among the sections of the switchboards that the work is distributed as uniformly as possible amongst the different operators.

The dry-core or paper insulated cable has proved to be a very great success, and is now universally adopted for telephone purposes.

Chicago.

I have gived the number of exchanges and subscribers in Chicago. To provide for this service there are—

Miles of conduit	48·02
Miles of duct, or channel	433·24
Miles of cable, underground	106·96
Miles of wire, underground	17,995·53
Number of manholes	888·0
Miles of cable, aerial	65·97
Miles of wire in aerial cables	5,184·70
Total miles of wire in cables	23,180·23
Total miles of wire on poles	7,958·0

Switch-Boards and Indicators.

Great improvements in working have been made in consequence of the introduction of metallic circuits. Visual signals, like those employed by the Post Office Department, are coming in. Dirt in the gear was a great source of trouble. False busy signals were frequently received. Now a third wire and an automatic restoring indicator has made the busy test reliable. The visual signals on trunk wires are assimilating the American working to our Post Office system.

Disturbances.

The disturbances in telephone circuits created by the extension of electric railways have been severely felt in many parts of the United States. We have experienced the same in London, Liverpool, Leeds, and Blackpool. But owing to the prompt action taken by the telephone companies, especially in Boston, the area of disturbance has been much reduced, and the influence of electric railways on telephones has ceased to be a trouble. Of course this result is very much favoured by the rapid introduction of metallic circuits into cities; but it has also been favoured by the prompt action of the railway companies themselves. They did all that they were asked to do, and that at once. In all cases the negative pole of the dynamo at the generating station is put to earth, and the return conductors have been enlarged. Extra copper wires have been buried between the rails, and heavier conductors have been put upon the poles. The return conductor is the largest size copper wire made, viz., No. 0. The rails have been bonded together and to this return conductor; and in Boston the rails are welded electrically, which is very effective. I was, unfortunately, unable to see this electric welding in operation, for the transformer had broken down, and was in the shops under repair. I saw the whole apparatus, however. A special car is used for the plant, and the system adopted is extremely satisfactory. The electrolytic action of these disturbing currents has been noticed, not only as affecting gas and water pipes, but also the lead coating of the telephone companies' cables. I have seen several specimens of lead pipes much pitted. I have reason to believe that the remedies adopted to cure disturbance will also put a stop to what might have become an element of great danger to underground cables.

Lightning Protection.

A very efficient system of lightning protection has been introduced upon the telephone system, not so much to protect the system from the effects of lightning, as from the effects of those powerful stray currents that enter a telephone circuit when accidental contacts occur between it and electric light and electric railway conductors. Such contacts have been frequent, owing to the prevalence of overhead systems, but they are diminishing now that conductors are placed underground. They have resulted in numerous accidents, and several telegraph and telephone offices have been set on fire and the apparatus destroyed. Every telephone circuit is now protected by a fuse, or cut-out—a fine wire of great resistance, which melts if traversed by a powerful current; also by an air space protector on the same principle as the lightning arresters we use, but having carbon plates instead of brass plates; and, finally, by a small heat coil, which puts the current to earth in a very ingenious way when the stray currents exceed a certain strength. These three guards have been found quite effective. No accident has occurred where they have been used.

(To be concluded.)

THE FERRANTI EFFECT.

The following abstract of an article by Dr. Sahulka in a Viennese journal is published in the *Elektrotechnische Zeitschrift* of December 29th last.

If the secondary circuit of a transformer, whose primary is on an alternator, be coupled to a condenser of suitable capacity, the ratio of transformation rises under certain circumstances above the ratio of the primary and secondary turns, while the primary volts rise and the current falls; and this is one of the most remarkable of the "Ferranti Effects." Dr. Sahulka begins by showing theoretically that this phenomenon has for sole cause the leakage of induction in the transformer, and describes some experiments which tend to support this theoretical conclusion. Supposing L_1 and L_2 to be the coefficients of self induction of the two circuits and M their mutual induction, and if N_1 and N_2 be the respective numbers of turns, then in a perfect transformer (that is, one in which there is no magnetic leakage)

$$M^2 = L_1 L_2,$$

and, therefore, with high resistance in the secondary circuit the ratio of transformation

$$U = N_2/N_1.$$

But, on the other hand, if the transformer be not perfect, a magnetic leakage takes place, then M^2 is less than L L_1 L_2 and U is less than N_2/N_1; that is to say, that in this case the ratio of transformation may be considerably less than the ratio of the numbers of primary and secondary turns.

If the secondary circuit, on the other hand, be closed through a circuit of capacity, C, then L_2 becomes $L_2 - 1/(2\pi n)^2 C$, where n is the frequency. The perfect transformer gives also in this case a ratio of transformation, $U = N_2/N_1$; but if leakage of induction takes place, the U is greater than N_2/N_1. In this case, therefore, the ratio of transformation is raised, and depends on the capacity of the condenser. The apparent resistance of the primary circuit also rises, and also the primary electromotive force of the transformer, and the primary current goes down.

In the experiments a transformer with straight cylindrical core of iron wire was used and wound on a quarter of its length with four layers of copper wire of 73 turns each, and on the remainder with four layers of 219 turns each. If the former was used as primary and the latter as secondary of the transformer, then the leakage was naturally very great, and the ratio of transformation, therefore, much less than the ratio of the numbers of turns. On open circuit the ratio of transformation was only 1·38. Under these circumstances, if a condenser of 5·15 microfarads was switched into the secondary circuit the ratio rose to 1·63, the increase being 18 per cent. If the primary and secondary were superposed, the primary being 292 turns outside and the secondary 876 turns inside, the leakage was naturally much diminished, and the ratio of transformation became 2·70 on open circuit and 2·74 with condenser, the rise being only 1·5 per cent.

There is, therefore, says the author, no doubt that the Ferranti effect is due entirely to magnetic leakage or "drop" in the transformer, and that, therefore, where there is no such leakage the rise cannot take place.

The Preservation of Belts.—The following empirical formula for a machine belt preservative is due to *L'Industrie*:—Warm in a covered vessel to a temperature of 50°C., 1 kilogramme of india-rubber broken up into pieces and mixed with 1 kilogramme of essence of turpentine. After the rubber has melted add 800 grammes of colophone; stir until this too is dissolved, then add 800 grammes of yellow wax. In another vessel put 3 kilogrammes of cod liver oil, and 1 kilogramme of tallow; heat this mixture until the tallow melts, and then pour it into the first vessel, stirring continually until the mass cools and solidifies. Belts, the working faces of which are occasionally treated with this compound, are said "to acquire greater solidity, and slipping at the pulleys is avoided."

HISTORY OF THE TELEPHONE IN CANADA.*

BY L. B. M'FARLANE.

As the object of this Association is not only to foster the science of electricity, but to conserve its records, I have ventured to deviate from the usual plan adopted by members in their Papers, of dealing wholly with the scientific aspects of the subject, and offer instead a brief historical sketch of the telephone in Canada—the country that can with truth be called the birthplace of the telephone. Prof. Alexander Graham Bell's home was, for several years prior to the invention of the telephone, at Tutello Heights on the outskirts of Brantford, Ontario, and it was there that many of his experiments in multiple telegraphy, and some of the earliest in telephony, were made. The first experimental telephone line erected in Canada and used in this connection extended from the residence of the inventor's father across his garden. This line being found workable, it was afterwards continued on to the residence of the Rev. Thomas Henderson, in Brantford. Its successful working soon became noised abroad, and the novelty of the invention attracted many visitors from various parts of Ontario, to listen to the then wonderful performance of the electric telephone, and presently Brantford became known as the "Telephone City." At this time the much-condemned "Hello" had not come into use as a signal for conversation to begin; the words, "Hoy, Hoy," were considered most satisfactory. We must give a discriminating public the credit of choosing the less objectionable word, and be thankful that "Hoy, Hoy," did not survive. When the Canadian patent was issued to Prof. Bell he presented it as a gift to his father, Prof. Melville Bell, and the latter, believing a company or partnership unnecessary, appointed a general agent to exploit the Bell telephone. The latter visited the principal cities and towns, and exhibited the old-fashioned box telephone, with but little commercial success, however, as the difficulty of hearing the voice clearly rendered problematic its future value as a means of communication.

The first commercial telephone line was established at Hamilton, Ontario, in October, 1877, by the District Telegraph Company, who were quick to appreciate its value, and they, therefore, secured control of the invention for that district. This line connected together the residences of Messrs. Baker and Cory.

Mr. Edison at this time was not neglecting Canada as far as telephony was concerned. He had opened up correspondence early in 1877 with the City Electrician of Montreal, and forwarded two sets of his telephones for trial. These were placed on the telegraph line between Montreal and Quebec, a distance of two hundred miles, and worked with remarkable distinctness, notwithstanding the presence of several relays in the circuit.

On September 15, 1877, a contract was entered into between these gentlemen, whereby the latter secured the sole and exclusive right to the telephonic inventions in Canada of Mr. Edison for a nominal sum, with the option of purchasing outright the patents for the sum of $10,000.

The element of competition was thus introduced at the outset of the business. Both parties claimed priority of patents, and threatened suit against all and sundry users; but while this rivalry continued until 1880, it was not known that Edison as early as 1877 had admitted Bell's claim to priority. This he did in a letter to his Canadian representative, under date of October 13, 1877, wherein Mr. Edison stated that:—"Bell has done absolutely nothing new over Reiss, except to turn Reiss's from a contact breaking into a non-contact breaking telephone with permanent magnet, and worked the thing up to a success. The records of the patent office will show that myself (Edison), Bell and Gray started nearly together on acoustic telegraphy for Morse working, that Bell and myself dropped this for speaking acoustic, and that I dropped it first and was working on it before Bell. However, Bell got ahead of me by striking a principle of easy application, whereas I have been plodding along on the correct principle, but harder of application."

The cry of infringement failed to deter lessees from using the telephones, and numbers of private lines were erected in Montreal and Toronto. These lines formed the nucleus of exchanges in these cities, which were first put into operation in 1878. Montreal was equipped with the Edison apparatus, while the local company operating at Toronto adopted the Bell instruments. The Blake and Edison transmitters having been introduced, the business began to show some development. The Western Union Telegraph Company, through its ally, the Gold and Stock Telegraph Company, secured in 1878 control of the Edison patents for Canada, and the Montreal Telegraph Company were appointed agents for Ontario and Quebec, and the agents of the Western Union Telegraph Company in the Maritime Provinces were ordered to look after the telephone in the lower Provinces. In telegraphic circles it was thought that whoever could control the telephone could command the bulk of the telegraph business, and the telephone was used principally as a lever to this end. The Dominion Telegraph Company, then in fierce competition with the Montreal Telegraph Company, became alarmed at the apparently shrewd move on the part of its rivals, and immediately set about securing exclusive rights of the Bell telephone as a weapon of defence. Negotiations resulted in a contract between the patentee and the Dominion Telegraph Company, and the three telegraph companies started in a race to secure subscribers to their exchanges in the cities and towns from Windsor to Halifax, where exchanges inaugurated by local companies did not already exist. Some cities were, however, slow to appreciate the use of the telephone, notably Ottawa and St. John, N.B. At Ottawa an active canvass was commenced, but in order to save time a complete telephone exchange outfit was shipped there; the canvass was unsuccessful, no subscribers were forthcoming, and the plant had to be stored until the public could be educated into the use of the telephone. At St. John only one subscriber could be secured after two weeks' canvassing. A brilliant idea then occurred to the manager of the opposing company at this point, and was carried to a successful issue. It was to open a free telephone exchange, on trial. This at once demonstrated the necessity for an exchange, and soon two competing exchanges were working, and unable to keep pace with the paying orders offered.

This struggle between the telegraph companies, which signally failed in its main object of diverting telegrams to any one company, resulted not alone in cutting telephone rates to absurdly low figures, but in doing business absolutely without charge. To such competition there could be but one end, and it was soon reached. There had been a large capital outlay, and the revenue did not by any means meet the expenses. A proposition at this time to form a separate telephone company, independent of all telegraph companies, was made. The suggestion was gladly accepted by the interested companies and patentees, and by the public at large, who were suffering in most cities from the annoyance of two telephone exchanges. The Bell Telephone Company was thereupon organised and incorporated in 1880, when it took over all the existing plants and patents, reorganised and consolidated the exchanges, and began the manufacture of all kinds of telephonic apparatus.

The work of constructing lines connecting adjoining places was begun on the single-wire plan, and towns and villages within a radius of one hundred miles were given direct means of telephonic communication. This added to the value of the exchanges, and as the business prospered a question was raised by interested parties, anxious to embark in the business, as to the validity of the Bell patent. Two telephone companies were formed by these parties, and local competition at a few points ensued. The patent dispute was brought before the Minister of Agriculture at Ottawa, and the patent was lost to the Bell Telephone Company in 1885. A similar fate befell the Blake Transmitter Patent, and as the Minister's decision was final and irrevocable, the telephone field was opened to all comers. Notwithstanding this blow, the Bell Telephone Company continued to rapidly increase its list of subscribers and revenue, and their competitors were left to the tender mercies of their creditors, who found the venture, while it succeeded in breaking the patents, had proved an unprofitable financial undertaking. Later on competition appeared in several localities, but as the connections of these opposing concerns were necessarily limited, they again demonstrated the inutility of working a duplicate telephone system in a city or town, by disappearing from the scene without ever having paid a dividend.

A local company was formed in Nova Scotia and New Brunswick, and after a short struggle with the Bell Telephone Company an agreement was arrived at, whereby each of these provinces would have a separate telephone company, the Bell Telephone Company withdrawing from the field, but retaining an interest in each company. These companies have covered their territories with trunk lines and exchanges. The local company of Prince Edward Island, which had previously been formed by the Bell Telephone Company, has, however, reached the highest stage of expansion, it having a network of wires which reaches every town and village on the island. The Bell Telephone Company were early in the field in Manitoba and the North-West, and have kept pace with the development of this territory, by opening stations at all points where business would warrant. British Columbia is served by local companies, using the same type of instrument as Eastern Canada. These companies have been most energetic and progressive in their policy. As an indication of this we can note the fact that Vancouver, B.C., was the first exchange in Canada to alter its entire system at great cost, and give each subscriber a separate metallic circuit line.

Canada has kept pace with all the advances in the art of telephony. Metallic trunk lines between towns in Ontario and Quebec were erected and put in operation when the system was first introduced into the United States, and all the best and most modern switching and signalling appliances have been furnished, thus ensuring to the public a most reliable service. On some points it may be said that Canada is in advance of other countries;

* Paper read before the Canadian Electrical Association, September 12, 1893.

Digitized by Google

notably in the use of the system of duplexing telephone trunk lines, which is now in operation in Toronto. The vast number of country trunk lines, both metallic and single in the older provinces, show that the service is appreciated and used by all classes of the community.

LEGAL INTELLIGENCE.

The Medical Battery Company (Limited).

C. B. Harness, the managing director of the Medical Battery Company, J. M. M'Cully, and C. B. Hollier surrendered to their bail before Mr. Hannay at Marlborough-street Police-court on Wednesday to answer the charges of having conspired together to defraud divers persons.

Mrs. CRAWSHAW, of Victoria-street, S.W., re-examined, said she attended the Court because she was interested in the case and grateful for the benefits she received from the treatment at Oxford-street. She offered to give evidence for the defence. She was quite satisfied with the treatment she received, and her feeling of gratitude still continued.

Mr. RICHARD ELLIOTT, a theatrical agent, of Greyhound-lane, Streatham Common, said that in June, 1891, he was suffering from laryngitis and nervous exhaustion, brought on by overwork. He consulted various medical men to get relief. Among them was Sir Morell Mackenzie. He derived no benefit from their advice. He therefore went, on June 29, 1891, to the Medical Battery Company, Oxford-street, when he saw Hollier. He told him what he was suffering from, and was recommended to undergo a course of electrical treatment. Hollier recommended him to wear a belt, and told him he would have to be under treatment for some time. It was arranged that he should pay a fee of 100 guineas, and that he should continue to visit the establishment until he was cured. He paid the money by cheque, and was than introduced by Hollier to Dr. Brabant. He visited the place three times a week, and was under Dr. Brabant's care. He was "massaged" and inhaled ozone. The result of the treatment was that he soon began to improve, and eventually he was restored to health. Altogether he went to Oxford-street between 70 and 80 times. Each time he visited the place he was under treatment for about three-quarters of an hour. He was perfectly satisfied with the treatment he received.

Cross-examined: He was not recommended to go to Oxford-street by anyone. He went there after reading the advertisements, and because he believed in that kind of treatment. Hollier told him that the 100 guineas must be paid in advance, and when he informed him that he had not his cheque-book with him, he believed Hollier said, "That does not matter; we can supply you with a form."

EDWARD CHURCHILL, of Manor-place, Walworth, manager to a firm of builders, deposed that since he was 18 years of age he had suffered from lumbago and piles. On the recommendation of a friend he purchased, in October, 1889, a Harness belt, paying three guineas for it. He wore it next his skin. He had worn one ever since. Since wearing the belt his ailments had disappeared, and his general health had improved. Before he wore the Harness belt he used a flannel belt, which did him no good. In December, 1892, he wrote a letter to the Medical Battery Company recounting the benefits he had received from wearing one of their belts.

WILLIAM HARKET, ex-police sergeant: While in the force he received an injury. About six months ago he suffered badly from cramp and congestion of the liver. He went to Oxford-street, and he purchased a belt for £4. 10s. During the last 16 years he had suffered from serious complaints, and had consulted medical men as to his condition. He wore the belt he purchased next his skin. After wearing it for two or three days it caused irritation, and he then put a handkerchief over the irritation, which disappeared. The result of wearing the belt was marvellous. Five hours after he first put it on he felt a warmth come all over his body. The next day he felt better and more cheerful. The cramp disappeared altogether, and he continued to improve in health. About two months after he had the belt he left off wearing the belt next to his skin, and then he became unwell again. He, therefore, put it next to his skin again, and almost immediately got well. He continued to wear the belt, and had not the slightest doubt that it cured him.

JOHN MARCHANT, 72 years of age, gave similar evidence.

Mr. HANNAY: Have you many more witness to call, Mr. Avory?

Mr. AVORY: Yes, Sir.

Mr. HANNAY: Then I do not think that I need trouble you to call them. I should like, however, to give Mr. Terrell an opportunity of saying how he thinks the evidence called for the defence affects his case.

Mr. TERRELL said he held that there was a *primâ facie* case for a jury.

Mr. HANNAY, in announcing his decision, said that after giving much time and thought to the case he had come to the conclusion that if it were sent for trial, no jury would convict. He was anxious that the full facts should be put before him, because he thought such a case might have been a test case, which would have had a very wide application. He should not have allowed the case to go on for such a long period had it not been that there was a great deal in the conduct of the business of which no honest man could approve. The practice of extracting large sums of money from persons who went to consult Mr. Harness was most reprehensible, for, although the management at Oxford-street had some reason to believe in the value of their appliances, they must have known that they could not be successful in every case. The two main circumstances upon which a jury might have been asked to draw an inference of guilt were the manner of conducting the business by exacting large sums of money down; and, secondly, the fact that the actions against *Science Siftings* and the *Electrical Review* were settled without being taken into Court. He could well believe that there were points in the conduct of the business which the mangement were most unwilling to have exposed to the full light of day. In defence of the practice of exacting large sums of money from patients it was said that it was done to make the patients give the system a fair trial. He must remark that several of the witnesses called by the prosecution were indifferent witnesses, as their memory appeared to have failed them. For the defence a number of witnesses of education and good sense were called, who stated that the treatment they received cured them. It was said by the prosecution that they could not have been cured. It seemed to him to say very little for the electricians, who declared that these things could not cure, while these witnesses swore that they did cure them. To make a case indictable there must not only be knowledge, but a guilty knowledge. These people at Oxford-street received numerous testimonials from persons who said they were benefited by the treatment they received. How was it possible to ask a jury to say that they knew all the time that these things were valueless when they were receiving constant testimonials as to their value? That was the real issue in the case. A regular record of the payments received appeared to be kept; there was no sort of concealment about the amount of the money received; and they invited medical men, the Royal College of Physicians, and the Royal College of Surgeons to visit the establishment and to inspect the appliances. He would just like to say one word regarding the chances of conviction. It was remarkable that, although they daily saw advertisements of quack medicines supposed to cure all sorts of diseases, no action had been taken by the Director of Public Prosecutions against the persons who issued such advertisements. He thought that if he had seen his way clear to get a conviction the Public Prosecutor would have undoubtedly intervened in such cases. What was still more remarkable was that in Scotland, where there was an effective Public Prosecutor in every district, no prosecution of the kind had ever been instituted. The only case like the present one was the recent prosecution of Indian oculists, which did not result in a conviction. The learned magistrate then discharged the defendants.

Mr. TERRELL asked that he should be given 24 hours to consider whether his clients should be bound over to prosecute under the Vexatious Indictments Act.

Mr. AVORY asked that the recognizances should be fixed at a sum of not less than £1,000. He should like to know who the real prosecutor was.

It was eventually arranged that Mr. Terrell should be allowed a week to consider whether proceedings would be taken under the Vexatious Indictments Act.

Edison-Bell Phonograph Corporation (Limited) v. Smith and Another.

This was an action before Mr. Justice Wright, in the Queen's Bench Division, and was brought in respect of the alleged infringement of a patent taken out by Mr. Edison in 1889, relating to phonographs. The defendants were Mr. G. A. Smith, of Hove, Brighton, and Mr. J. L. Young, of Fore-street, London, E.C., who pleaded that the plaintiff Company's patent had been anticipated by a previous patent taken out by Mr. Edison, and which had lapsed by the effluxion of time. It is claimed by the plaintiff Corporation that Mr. Edison in the patent which is the subject of this action claimed that it substituted one diaphragm for two, and that this alteration, together with other improvements, had made the phonograph a commercially useful machine, because of its easier adjustment.

Sir R. Webster, Q.C.; Mr. H. Fletcher Moulton, Q.C.; Mr. Bremner, and Mr. J. C. Graham appeared for the plaintiffs; and Mr. R. B. Finlay, Q.C.; Mr. Bousfield, Q.C.; and Mr. L. Edmunds for the defendants.

Sir R. WEBSTER, in opening the case, stated that Mr. Edison, with a colleague, had, about 1878, worked out the idea of the phonograph, but that their investigations were interrupted by other business, chiefly in connection with the telephone, and that the experiments with the phonograph were not resumed until about six years ago. The question of adjustment was the very essence of success so far as the phonograph was concerned, the instrument being one of extreme delicacy. A practical obstacle to a commercial phonograph was the difficulty to be overcome in very minute points, as any irregularity of pressure, or irregularity of cut, would render the instrument of small commercial value. The principal claim in Mr. Edison's invention was the replacing of the double diaphragm by a single diaphragm, this doing away with the necessity for using frames separate from one another, each governing its own tool, one the recording tool, the other the reproducing tool. From a commercial point of view the question of failure or success depended upon the adoption of the single diaphragm. This, however, was not effected without creating minor difficulties, which Mr. Edison had successfully combated by an invention which, although subordinate, was of considerable merit. Several other ingenious contrivances adopted by Mr. Edison were included in the patent which the plaintiff Corporation claimed had been unduly infringed by the defendants.

Several witnesses were called in support of Sir Richard Webster's case, amongst these being Dr. John Hopkinson, and, after hearing witnesses in support of the defendant's case, Mr. Bousfield summed up on behalf of his side, and the further hearing was adjourned till to-morrow (Saturday).

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Notice is given that the transfer books and registers of members will be closed from the 10th to the 24th inst. inclusive. Subject to the completion of the audit, and after making the necessary provision for repairs, maintenance, renewals and reserve funds, the Directors, out of the profits for the year ended 31st December last, will recommend the payment of the full dividend at the rate of 6 per cent. per annum on both issues of the preference shares of the Company, payable on and after the 23rd inst., carrying forward a substantial balance to next account.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 20, 1894.

Prof. Rowland and the Cataract Construction Company.—As we write, the case of Prof. Rowland against the Cataract Construction Company, claiming $30,000 for professional services rendered in connection with the Niagara plant, is being tried in a Federal Court in New York. Prof. Rowland submitted a bill of $10,000 for his services, but was only allowed $3,500, which he refused, and began suit for the sum named. Prof. Rowland was in the witness-box for parts of two days, and claimed that his recommendations in regard to low-frequency, step-up transformers, heavy moving parts in dynamos, and awarding the contract to the Westinghouse Company, were followed, as well as other points relating to design and distribution. On cross-examination it was developed that the Professor had recommended 33 periods per second, and the counsel for the defence claimed in his opening address to the jury that not a single point had been specified in the completed plans that could be claimed as distinctively originating with the plaintiff. Prof. Rowland was severe in the condemnation of Prof. Forbes, whose plans he described as foolish and puerile, and whom he characterised as ignorant and partisan. Mr. Joseph H. Choate, who is generally accounted the leading American barrister, was unsparing in his examination of Prof. Rowland and his witnesses. The adroit lawyer took advantage of a phrase in a letter from Prof. Rowland to the Presisident of the Cataract Construction Company, in which the Professor stated that he was the "first physicist and electrician in America," and ironically used the expression on every occasion. In reply to a question, Prof. Rowland stated that Lord Kelvin was a greater physicist and electrician than he, but appealed to the Court when asked if he was a greater physicist and electrician than Mascart, who, in reply to a question, he stated was exceeded in reputation by many others. The defence claims that the amount tendered Prof. Rowland is greater in proportion than he ever earned before, and larger in amount than paid for the services of Profs. Forbes and Sellers for the same length of time, and Mr. Choate added that a deduction should be made for the time spent in writing letters to the officers of the Construction Company vilifying Prof. Forbes. The witnesses for the plaintiff, Dr. Duncan, Dr. Jacques, Prof. Baker, and Mr. F. J. Sprague, testified that the amount demanded, $30,000, was not excessive in view of the eminent standing of Prof. Rowland and the time spent by him (six months) on the work. As we write this the examination of the witnesses for the defence has commenced.

The American Institute of Electrical Engineers.—At the eighty-third meeting of the American Institute of Electrical Engineers, Dr. Bell read an important Paper on "Practical Properties of Polyphase Apparatus," which was followed by a most interesting discussion, in which Mr. C. P. Steinmetz is generally conceded to have carried off the laurels. Among the points considered in the Paper are the relative merits of two and three-phase motors with reference to their torque, both starting and normal, and mechanical features. The subject of frequencies was also discussed with relation to lighting and power. Messrs. Wm. Stanley, jun., O. T. Crosby, C. P. Steinmetz, Pupin, C. O. Mailloux, and others took part in the discussion. Mr. Steinmetz traced the history of the rotary field from Arago, and in disputing Mr. Stanley's remarks against synchronous motors and in favour of condensers, said that motors of the synchronous type, if properly designed, have sufficient condenser action of their own. In regard to frequency, he said that his experiments showed that with high voltage incandescent lamps burned with usual brilliancy, the flickering was exceedingly disagreeable at 20 periods, and was still manifest at 30 periods.

BOOK RECEIVED.

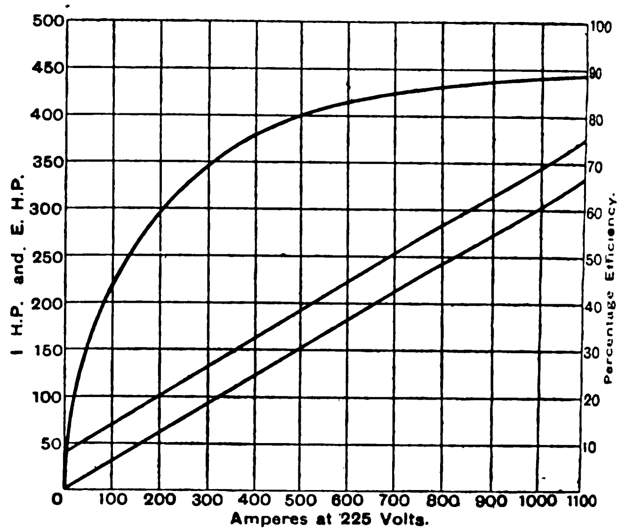
"The Inventions, Researches, and Writings of Nikola Tesla." By Thomas Commerford Martin. (Published by the *Electrical Engineer*, New York.)

CORRESPONDENCE.

A SIEMENS-WILLANS SET.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We venture to think that the figures in the enclosed table are of some interest, as, to the best of our knowledge, so high an efficiency as 88 per cent. has not been previously



obtained. The tests were made at the works of Messrs. Willans and Robinson, under the superintendence of Prof. Kennedy, the consulting engineer. The curve which we enclose is also remarkable.

Test of Siemens-Willans Set for Glasgow Corporation.

SAFETY FUSES IN HOUSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to endorse your remarks in a paragraph of this week's *Electrician* on the carelessness shown by wiremen in fitting fuses in private-house installations. Apparently the fuses are put in without the slightest regard to the number of lamps they are to carry; or, if any thought is expended on the matter, it is rather in the direction of trying to limit the consumer in the number of his lamps that he may light at one time, the fuse being adapted to the average load instead of the full load. In a house at which I was spending the evening a few days ago, the light was suddenly extinguished, and investigation showed that the main fuse had melted. There were about 70 lights in the house, while the fuses were for 35 lights, with the natural result that, on the first occasion on which the house was extensively lighted up (the lady of the house was giving a ball), the whole place was put into darkness. It seems, of course, a small matter to an electric light engineer that a fuse should go, but to the average householder the failure is as serious, so far as he is concerned, as a complete breakdown of the central station, for the mysteries of cut-outs are at present beyond his range of knowledge. In this particular case I was able to put the matter to rights in a

Digitized by Google

few minutes, but if I had not chanced to be present the entertainment must have forthwith come to a conclusion.

As mistakes like this go far to discredit the electric light, and in an absolutely unnecessary way, I should think it would be to the interest of the electric supply companies to inspect the fuses occasionally at the time when the meters are inspected. The wireman does not care about the matter, as he has finished his job, and he probably puts in any fuse he happens to have with him. The same carelessness I have also noticed on branch circuits. In one case a set of six lamps were run on a No. 22 tin fuse wire, or single-light fuse, which must have been in a semi-molten condition every time the lamps were lighted, and which eventually broke with a slight increase of pressure on the circuit. Instances such as these give the enemy opportunity to blaspheme, and exert a powerful moral effect in deterring people from unreservedly adopting electric light. They are but two examples out of many, and in both cases the firms which had carried out the wiring were experienced and capable.—Yours, &c,, FRANCIS G. BAILY.

University College, Liverpool, January 26, 1894.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "'THE ELECTRICIAN' ELECTRICAL TRADES' DIRECTORY AND HANDBOOK" will be published on Friday next. Printed particulars and List of Contents can be obtained, post free, from "The Publisher," *Electrician* Office.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

TENDERS INVITED.—The Scarborough Corporation invite tenders for lighting, by electricity, the council chamber, court house, offices, &c., in the Town Hall. Tenders have to be in by 12 o'clock on Monday next.

VACANT APPOINTMENT.—The School Board for London require a stoker competent to take charge of dynamos and steam-engines in the absence of the engineer. See advertisement columns for further particulars.

LIQUIDATIONS.—At meetings held on January 5th and 23rd the shareholders of the Electric Arms and Ammunition Syndicate (Limited) resolved that the company be voluntarily wound up. Mr. E. F. Hunt, 17, Throgmorton-avenue, E.C., was appointed liquidator.

———— We have received the following from the Secretary of:—

"LATIMER CLARK, MUIRHEAD AND CO., (LIMITED).

"I regret to inform you that the Debenture-holders of the Company having taken action and obtained the appointment by Mr. Justice North of Mr. James Worley as Receiver and Manager of this Company's property and business, it is impossible for the Company to pay the debts as they fall due, and the shareholders have therefore passed a resolution for the liquidation of the Company, and Mr. Worley has been appointed liquidator. I have therefore to request that you will send to that gentleman, here or to his office, 27, Leadenhall-street, particulars of your claim. Meantime, with the authority of the Court, Mr. Worley is making arrangements for the completion of pending contracts, and the Directors hope the realisation under the circumstances may be favourable. If you desire any further information, the Receiver will no doubt supply the same, or you can apply to Messrs. Bircham and Co., Winchester House, Old Broad-street, E.C., the solicitors for the plaintiff in the Debenture action, or to Messrs. Trinder and Capron, 47, Cornhill, E.C., the Solicitors for the Liquidator."

———— Mr. Justice Wright, on Wednesday, sanctioned a scheme of arrangement which had been agreed to in respect of a petition for the compulsory winding up of Elmore's French Patent Copper Depositing Company (Limited).

———— Mr. Justice Wright, on Wednesday, made an order for the compulsory winding up of R. Bolton and Co. (Limited).

———— A petition for the compulsory winding up of the Platinum Plating Company (Limited) was, on Wednesday, ordered to stand over for three weeks.

BANKRUPTCY.—Creditors of Messrs. Austin and Myers, lately carrying on business as manufacturing electricians, at 7, Florence-terrace, Armley, near Leeds, must send in proofs of their claims by the 20th inst. to Mr. J. Bowling, Leeds, the Official Receiver.

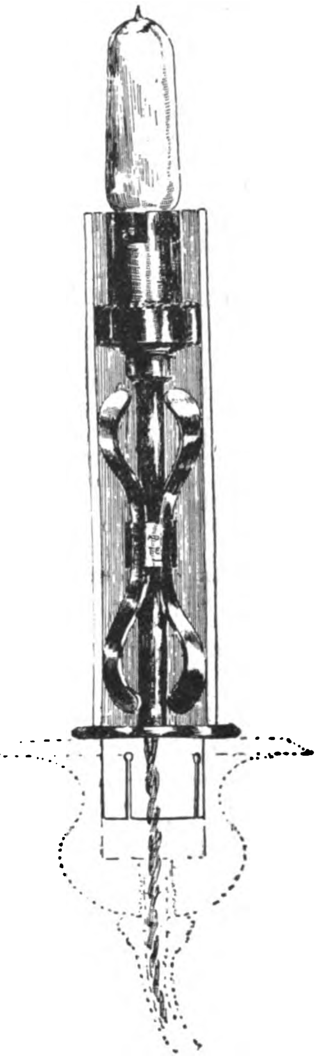
———— At the Liverpool Bankruptcy Court, on Friday, the discharge of Charles Walter Cox and Frederick George Robinson, formerly carrying on business as electrical engineers in Liverpool, was suspended for a period of two years.

DISSOLUTION OF PARTNERSHIP.—Messrs. Roberts and Mundy, trading as the North London Battery Company, electricians, 41, Hawley-crescent, Kentish Town-road, N.W., have dissolved partnership.

CHANGE OF NAME.—The Executive Committee of the City and Guilds of London Institute have changed the name of the Guilds "Central Institution" in the Exhibition-road, London, S.W., to the Guilds "Central Technical College."

MESSRS. C. A. PARSONS AND CO.—We are requested to state that by mutual arrangement, Mr. A. A. Campbell Swinton has ceased to represent Messrs. C. A. Parsons and Co., and in his place Mr. C. P. Martin has been appointed their London agent. Messrs. Parsons and Co.'s London office will continue to be at 66, Victoria-street, Westminster, as previously.

MESSRS. FARADAY AND SON.—A "Crystal Star Pendant" has been designed by this firm for ceiling lights in high rooms. It is suited to hang to the finials or hammer beams of large halls and dining-rooms, or in high conservatories. To obtain the best effect



Faraday's Candle Fitting.

with this arrangement the point of light should be as small as possible, hence it is generally used with the clear bulb lamp of 1in. or $1\frac{1}{4}$in. diameter. At a height of 12ft. or more the light is so refracted and transmitted by the cut-glass facets that it becomes a complete star in appearance, and, since it is placed so far above the line of horizontal vision, the full power of an unscreened electric light is made available without injury to the eye or annoyance to the senses. It is especially light and airy in appearance, when seen at a distance. A simple mechanical device has been arranged to afford support for the imitation candles, now so largely used in adapting the electric light to sconces and candelabra. The unsightly effect

Digitized by Google

of candles standing at various angles is thus overcome ; at the same time they may be easily removed for the needful cleaning without in any way interfering with the electrical connections. These latter are readily made at the outset, and are so protected that they cannot be put out of order. Reports having been spread that the patent of the adjustable, or "Perfect," pendant (Sir David Salomons' patent, No. 6,358, of 1886) had expired, Messrs. Faraday and Son desire to make it known that the renewal conditions have been periodically complied with, and that the patent remains in force. The advantages of this well-known fitting are obvious, and in its decorative forms it is now fit for service in any dining-room or library.

CHICAGO AWARDS.—There has been an unprecedented delay in announcing the awards made at the Chicago Exhibition. No list of awards has yet been issued, and it seems quite uncertain when one will be. Many awards have been announced, but none have as as yet been officially confirmed. Sir Henry Wood has, however, at different times, received information, from which it appears that about 1,400 awards have been made in the British Section. Of these 836 were in the industrial departments of the Exhibition, and were divided among 449 exhibitors. The total number of industrial exhibitors was 597.

"DUROL."—Under this name, a hardening liquid for steel is being introduced by Messrs. W. Holtz and Co. It is claimed that an unusual degree of hardness may be obtained by its use. The steel is to be brought to a dark red, dipped in "Durol" for 10 to 20 seconds, then heated slowly to cherry-red and quenched in "tepid" water. The temperature is given on the circular which we have received as 35°F. to 40°F., but on making inquiries, we have been informed that 15° to 20°Reaumur or 66°F. to 77°F. is intended. The composition is said to restore steel after it has been "burned," and is therefore probably of a case-hardening or carbonising nature. A sample which has been sent us by Messrs. W. Holtz and Co., has the appearance of a mixture of lamp black and a vegetable oil, but it seems to have a greater case-hardening effect on soft iron than such a mixture. For hardening steel it appears satisfactory. The inventor, we understand, defies analysis, and he is, therefore, perhaps well advised in declining to patent the composition.

THE ELECTRIC LIGHT ON RAILWAYS.—Speaking at the meeting on Tuesday of the Great Eastern Railway Company, Lord Claud Hamilton (the Chairman) stated, referring to the extensive new works at Liverpool-street station, that it had been decided to light the whole of that station, the hotel, the Bishopsgate low level station, the Bishopsgate goods station, and the the Bethnal Green Junction with the electric light, served and distributed by themselves. They had incurred for this purpose an expense of £35,000, which he did not think was large under the circumstances. In a very short time the whole of these stations would be lighted by the electric light, not only to the comfort of the public, but to the great benefit of those who served the Company. Messrs. Crompton and Co. are, we understand, supplying the plant for this contract.

ACME AND IMMISCH WORKS (LIMITED).—This Company, which is an amalgamation of the General Electric Power and Traction Company (Limited) and the Acme Electric Works, notifies the trade that in the amalgamated businesses the *employés* of the old firms have been retained, and the factory at Ferdinand-street, Chalk Farm-road, London, N.W., is to be equipped with suitable machinery for the manufacture of all kinds of electrical plant and apparatus, of which Immisch motors for lighting and other purposes, and mains and distributing switchboards, switches, cut-outs, &c., will be made a special feature. The new Company acquires valuable patent rights, machinery, and apparatus for the manufacture of all plant necessary for electric light and power contracts. Among the specialities which the new Company will continue to manufacture are the Cockburn switches, cut-outs, &c. Price lists are being prepared.

MESSRS. W. H. ALLEN AND CO.—This well-known engineering firm purpose transferring their factory from the York-street Works, Lambeth, where they have been established for many years, to the neighbourhood of Bedford, where they are building new works, owing to their present premises having been acquired by the London and South-Western Railway Company for the extension of their line. The new works at Bedford will probably not be completed until next year.

MESSRS. EASTON, ANDERSON AND GOOLDEN (LIMITED).—As announced elsewhere, the above Company was registered on the 26th ult., and is an amalgamation of Easton and Anderson—the old-established engineering firm of London and Erith—with Messrs. W. T. Goolden and Co., electrical engineers, of Woodfield Works, Harrow-road, London. The former firm, who for so many years have had an extended connection in hydraulic and general engineering work, have more recently been paying attention to the development of the electrical transmission of power. In their Erith works, for some four years, travelling cranes of 15 and 20 tons have been in work, driven electrically. A special department has also been established for the execution of various descriptions of electrical work. The firm of W. T. Goolden and Co. has been prominently before the public in connection with the application of electrical transmission in mines. The nature of the electrical work of each firm being so similar, the combination of the two should lead to an increase of business on both sides, as the new Company will be in a position to carry out all work in connection with large electrical installations, either for transmission of power or for lighting.

NEW BOOKS.—We are asked to state that Messrs. Crosby, Lockwood and Son will shortly publish the "Engineer's Year-Book," by H. R. Kempe. The book is to consist of about 600 pages, with nearly 700 illustrations.

CALENDARS.—Mr. Charles Rettie, of 18, Geraint-street, Liverpool, sends us a neatly-printed hanging calendar, with tear-off sheets. Mr. Rettie is sanguine enough to anticipate the early use of aluminium in ship building, a prominent feature of the calendar being a sketch of a ship built of aluminium and driven entirely by electricity.

ABERDEEN.—It is anticipated that the electric light will be inaugurated on the 19th or 20th inst., and Mrs. Stewart, of Banchory House, Aberdeen, has been asked to perform the ceremony, at which the Lord Provost, the magistrates, and Town Council will be present. The Public Library Committee have instructed Mr. Murray, the inspector of electric lighting, to report as to the cost of lighting the whole of the library premises by electricity.

BRISTOL.—A special meeting of the St. George Urban Sanitary Authority was held on Monday last to further consider the clauses of the Bill now being promoted in Parliament by the Bristol Tramways Company to put down additional tramways in the district. The Chairman proposed that the Board give their sanction to the Company's proposal to work the tramway on the overhead system. The motion was carried unanimously. A discussion followed as to the terms upon which the Tramway Company were to be permitted to lay the tramways, and it was pointed out that the success of the Company in its endeavour to obtain the necessary powers would hasten the adoption of the electric light in the district—at any rate, for the areas served by the Tramways Company.

——— The electric light has now entirely taken the place of gas in those thoroughfares where the electric light has been installed. Now that the Exhibition is closed there is more power available for private lighting, the demand for which has considerably exceeded the Electric Light Committee's anticipations.

CLERKENWELL.—The Vestry have received a communication from Mr. Sydney Morse, on behalf of clients, asking for certified copies of resolutions recently passed by the Vestry, with regard to an extension of time asked for in regard to the electric lighting scheme. Mr. Morse's clients are anxious to carry out the electric lighting of the district, and he therefore hopes that the extension of time asked for will be granted by the Vestry.

FINCHLEY.—The School Board is discussing the advisability of adopting the electric light in the schools in this distrtct, and Mr. Hardy, who has been asked to prepare a report as to cost, is to present this at the next meeting of the Board.

FOLKESTONE.—In reference to the electric lighting of Folkestone, Mr. C. O. Grimshaw, M.I.E.E., complains in a letter to the Town Council that only high-tension systems have as yet been considered. He asks that low tension may have a chance.

GLASGOW.—In reference to our Trade Note last week o c rriage lighting, we are asked to state that the batteries used are those made by the Bristol Electric Safety Lamp Works, of 63, Queen Victoria-street, London, E.C., and for which Messrs. Anderson and Munro, of 136, Bothwell-street, Glasgow, are the sole agents in Scotland.

HULL.—The Electric Lighting Committee of the Corporation at their last meeting had under consideration the draft resolutions submitted by the Board of Trade for the security of those using electricity from those who use the same power in connection with the working of tramways. Dr. W. Holder, chairman of the committee, said the matter was of the greatest importance to them in connection with their tramway scheme. Plans and estimates had been received from different firms for supplying a condensing service suitable for their station and its work, and after inspecting the tenders the matter was deferred until the next meeting.

KEIGHLEY.—A meeting of the Tradesmen's Association has been held, at which the question of electric lighting was discussed. It was complained that, some years ago, a private company was prevented introducing the light, owing to the action taken by the Corporation ; but that, notwithstanding five years had passed, the citizens were no nearer the attainment of an electric light supply, although much smaller places were being supplied. The newly-appointed President of the Association intimated that steps would be taken to bring the matter to a satisfactory conclusion shortly.

Digitized by Google

King's Norton.—The advisability of installing the electric light throughout the infectious diseases hospital and the whole of the rural sanitary authority's municipal buildings has been under discussion, and its further consideration has been adjourned for a month.

Lambeth.—The Vestry have decided to postpone, till after the elections in November next, the re-appointment of an Electric Lighting Committee.

Lancaster.—At the last meeting of the Local Board, the report of the surveyor upon the cost of lighting the streets by electricity was further considered, and it was resolved to place arc lamps of 1,000 and 2,000 c.p. in various main thoroughfares. Five 2,000 c.p. and eight 1,000 c.p. lamps were ordered to be fixed.

London County Council.—At their meeting on Tuesday last the Finance Committee of the London County Council presented a report on an application of the St. Pancras Vestry to borrow £30,000 for 42 years on the annuity principle, for electric lighting purposes. The Council had already sanctioned loans for £10,000 for the purchase of a site, repayable in 50 years, and £60,000 for works, repayable in 42 years. The £10,000 was advanced by the Council and the £60,000 borrowed elsewhere. On July 25th last they reported on the Vestry's application for a further loan of £30,000, when they recommended that the loan should be limited to £15,400. The Council concurred in their recommendation that the repayment of that sum should be spread over 42 years. The Vestry had not taken up this loan, and now renewed their application for the £30,000. The life of the different portions of the work having to be considered, the only satisfactory way of dealing with the present application appeared to be to consider it as part of an application for £90,000, on account of which £60,000 had been sanctioned. It must be borne in mind that an electric light undertaking differed from many other undertakings, in that a very large proportion of the total cost was in respect of works of a short-lived character. The Vestry contended that they should be allowed a longer period than one based upon the life of the work, in order that they might have equal advantages with an electric light company, which did not have to pay off its capital; but even if this be admitted, it must be remembered that a company could not borrow money at 3½ per cent., as the Vestry could, and that a company had to establish a reserve fund to meet depreciation and other contingencies. These considerations led to the conclusion that practically the only safe course for the Council to adopt was to sanction the loan for a term approximating to the life of the work. And there would be this advantage in the course suggested, that the Vestry would be justified in borrowing again for renewals. If the Council accepted this view, the present application might be granted as follows:—£2,500 for five years, £4,200 for eight years, and £23,000 for fifteen years, and in this event the resolutions of July 25th last, agreeing to sanction and lend the Vestry the sum of £15,400, should not be further proceeded with. They recommended accordingly.—Mr. J. Williams Benn, M.P., moved, as an amendment, "That the recommendation be referred back to the Finance Committee, with an expression of opinion that the total initial cost should be extended over a reasonable period, and without regard to the life of any particular portion of that which forms initial cost, and that the Finance Committee should be at liberty to take such professional advice, in addition to that of the officers of the Council, as the Committee may think fit."—Mr. McCall seconded this amendment, and, several other members having condemned the recommendation as being prohibitory to electric lighting being taken up by local authorities, the amendment moved by Mr. Benn was agreed to.

Madras.—Operations have been commenced for the laying of the Madras tram lines along the Esplanade-road. The central-power station at Madras is fast approaching completion, and one section of the tramway is to be pushed forward, and to be opened for traffic at the earliest possible moment.

Maidstone. —The Electric Lighting Committee of the Local Board, in response to inquiries from various quarters as to the terms upon which private firms or companies are prepared to carry out the installation of the electric light in the district, received five offers. These were considered at the last meeting, but no decision was arrived at, as further information on certain points was deemed necessary. The Committee anticipate reporting to the Board in a week or two.

Sutton (Surrey).—The Local Board contemplates transferring its Electric Lighting Order to a local company; but the Board of Trade decline to approve of the proposal until the transferee has been nominated, when the Department will require evidence of the latter's capacity to carry out the terms of the Provisional Order.

Wigan.—A meeting of the principal tradesmen in this town has been held to discuss the question of the adoption of the electric light, and it was pointed out that, unless the Corporation moved actively in the matter, there were amongst the citizens many who felt disposed to take the matter into their own hands, and to form a local company for the purpose. It was decided to prolong the time for tradesmen to reply to the circular issued by the Corporation on the subject.

Westmoreland.—Mr. George J. McKay, a prominent resident of Kendal, recently made a statement that he had saved £500 in five years by using the electric light. Several correspondents of the *Westmoreland Gazette* have called in question Mr. McKay's veracity; but in a letter to that journal he says he will be glad to demonstrate to any doubter how he saved £500 in five years, and he adds that his plant has not cost him £5 to maintain during the whole period, or less than £1 per annum.

————A proposal is to be placed before the next meeting of the Kendal Town Council from Messrs. R. H. Fell and Son (Limited) asking for the approval and consent of the Corporation to their application to the Board of Trade for a Provisional Order to supply electric current to the district.

Annual Dinner.—The fifth annual dinner of the *employés* of the Liverpool Electric Supply Company (Limited) took place on Saturday last, to which nearly 100 sat down, the chair being occupied by Mr. Clough, the works manager.

COMPANIES' MEETINGS AND REPORTS.

Liverpool Overhead Railway Company.

The following is the report of the Directors to be presented to the eleventh ordinary half-yearly general meeting of the shareholders, to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Tuesday, 13th inst., at 3 p.m.:—

In presenting the half-yearly statement of the capital and revenue accounts to December 31, 1893, your Directors have to report that the gross revenue receipts for the half-year amount to £18,518. 4s. 7d. The number of passengers carried were: First class, 260,221; second class, 1,295,840; workmen (special return tickets), 921,578—total, 2,475,639; making the total number of passengers carried since the opening of the railway, on March 6th last, 3,846,381. The electrical equipment continues to work very satisfactorily. During the past half-year 46,429 trains have been run, and 95.35 per cent. have been punctual. Your Directors have taken over from the Electric Construction Company the electrical working of the railway, from December 31, 1893, by which they hope to effect a considerable saving in the expenses. Progress with the northern extension was somewhat delayed by the coal strike, but the work is now well in hand, and it is expected to be completed about the middle of March. Under the powers sanctioned by the shareholders on August 8th last, £25,000 of the remaining Preference capital has been issued and fully subscribed.

The gross receipts from traffic ammount to £18,002. 16s. 11d.; miscellaneous receipts, £515. 7s. 8d.—£18,518. 4s. 7d.; less working expenses, £13,732 11s. 5d.—£4,785 13s. 2d. From which deduct interest on debentures and on calls paid in advance £2,627. 1s. 10d., and add balance brought forward from last half-year, £3,293. 9s.; leaving available for dividend the sum of £5,452. 0s. 4d. Out of this balance your Directors recommend the declaration of dividends at the following rates (less income tax), payable on and after February, 16th viz.: 5 per cent. per annum on Preference shares, £978. 13s. 3d.; 1 per cent. per annum on Ordinary shares £1,875—£2,853. 13s. 3d.; leaving a balance of £2,598 7s. 1d. to be carried forward to next half-year.

The Directors retiring by rotation at this meeting are Mr. James Barrow and Mr. Richardson Hobson, who, being eligible, offer themselves for re-election. The auditor retiring by rotation is Mr. George Nicholson, who is also eligible for re-election.

City and South London Railway Company.

The nineteenth ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, Old Broad-street, under the presidency of Mr. Charles Grey Mott.

The SECRETARY (Mr. W. F. Knight) read the notice calling the meeting, and the register of shareholders having been sealed, the report of the Directors was taken as read.

The CHAIRMAN: It now becomes my duty to move the adoption of the report and accounts. I am glad to be able to say that during the past half-year we have again carried the whole of our large number of passengers with absolute safety, and with almost absolute punctuality. As regards the number of passengers carried, there has been a slight check in the regular increase we have had every half-year, and you will notice, from the statement appended to the report, that as compared with the corresponding period of 1892, the decrease in the numbers carried has been 24,251, exclusive, however, of season ticket holders. There is an increase in the number of season ticket holders of 59, so that practically there has really been no decrease, but an actual increase in the numbers we have carried. The consequence is that the receipts have shown an increase of £65 in the half-year. We should undoubtedly have done very much better if it had not been for several special causes. I have always told you that fine weather morning and evening is always against the traffic of this line, and, as you know, during the greater part of the half year we had exceedingly fine weather both morning and evening in fact, there was hardly a wet morning or evening during

Digitized by Google

the whole of that time. Then, Kennington Oval has been closed for three months, and the football matches there are a considerable source of revenue to this Company. They are the best attended of any matches during the year, and we have, of course, lost that traffic, and I regret to say that we shall continue to lose it for another month or two. They are relaying the turf on the Oval, but when that is finished I hope that we shall get a better traffic on the railway. We have also undoubtedly suffered, in common with all the other railways of the kingdom, from the general depression throughout the whole of trade in the past year. Of course, we have not suffered in the same way as if ours were a goods line, because we have had no coal or goods to lose traffic on, but still that kind of depression of trade is always felt, even on solely passenger lines, and that is shown by the large decrease in passenger traffic all over the kingdom. We have not been idle during the half-year. The new sidings at Stockwell have been brought into use, so we have been able to give a better service and to decrease the overcrowding which was taking place in the morning and evening trains. The result has been, of course, that we have had to run an increased mileage, and we have run about 10,000 miles more than in the corresponding period of 1892. We have also introduced additional intermediate signals, and this has enabled us to run an increased service of trains, and thus we have been enabled gradually to relieve the overcrowding which was previously complained of. We have also been at work on the upper part of the King William-street station. That is now nearly completed, and in the course of the present month it will be opened for use. It will quite transform the appearance of that station, and make it much more attractive than it has been heretofore, and I hope in that way it will tend to increase the attractiveness of the line. We trust that the expenditure there, with the interest on it, will be recouped by the receipts we shall get from the left-luggage and parcels offices, &c. The conversion of the debentures into debenture stock has gone on, and we have paid off a large amount of the terminable debentures which became due just before the end of the year—to the amount, in fact, of £32,200, part of which has already been replaced by the Four per Cent. Debenture stock. We borrowed part of the money to pay these debentures off, but as they are replaced in the market by debenture stock, this loan will very soon be got rid of. The conversion is a permanent gain of interest to us. The bill for the extension to Islington, after a long delay, owing to the dissolution of Parliament, has been passed. A number of Bills, our own among the number, were carried over on the dissolution of Parliament to the next Session, on the suppersition that this would reduce their cost, but unfortunately it was found in practice that so far from reducing the cost it was increased considerable. Our Bill, however, passed this Session, and in one respect the delay was advantageous, for although we lost money by it, we gained a good deal—probably more than we lost—from the fact that during the delay we paid dividends on the ordinary stock and we are no longer paying interest on the deposit. We have also been able to relieve ourselves from the deposit. This will effect a future decrease of capital expenditure, which will compensate us for the extra cost caused by the delay. Turning to the accounts, and taking the capital account first, you will see that we have received on Preference shares for the half-year £400, and on Debenture stock issued £20,000; we have a loan of £22,000; and we have received a premium on Debenture stock of £616. These make a total of £43,016 received on capital account. During the half-year we have paid off £32,200 of the old terminable debentures; we have spent in connection with the Act of Parliament £4,400; the purchase of the adjoining house in King William-street—which you approved of last year—cost £2,827, and sundry other works (sidings, &c.) involved an expenditure on capital account of £3,144. These items make together a total of £42,571, leaving over expended the amount of £445. That disposes of the capital account, and now we come to the revenue account. The receipts from passengers show an increase of £61, compared with those of the corresponding period of 1892; parcels are £11 more: there has been a decrease in transfer fees of £4, rents show an increase of £39, and in sundry receipts an increase of £58 is shown, making a total net increase for the half-year of £168. On the other side, the expenditure shows an increase of £173 in maintenance; in locomotive and generating power there is a decrease of £535; carriage repairs show an increase of £13, traffic charges a decrease of £295, general expenses an increase of £14, law charges are £41 less, and there is a decrease in compensations of £66. That is not an actual decrease, because we insure against accidents, and this appears under the item of general expenses. Rates and taxes, as you know, are increasing half-year by half-year, and they show an increase this half-year of £101. The passenger duty is £5 extra. These items make a net decrease in the expenses of £629, and there being an increase in the receipts of £168, a net increase of £797 is shown in our revenue for the half-year, to which is to be added the £65 less that we have paid for debenture interest, thus making us £862 better off on the half-year. Last half-year the full dividend on the Preference shares did not come in, but it did this half-year, and there is an increase of £506 on that account, which would leave us £357 to the good for our Ordinary Stock. This time last year we paid a dividend on this stock of ⅝ per cent., taking £116 from the balance brought forward. This half-year we have increased the balance brought forward by £241, which makes up the £357 of the comparative increase. The working expenses are 64·6 per cent., against 67·9 per cent. in the corresponding period of the previous year. Deducting the cost of working the lifts, as we have done before, you reduce the actual working to about 55 per cent., which I think will be found to be less than most of the railways of the country. The receipts per train mile are exactly the same as they were at this time last year—namely, 2s. 0½d.—and the expenses are 1s. 4d., against 1s. 5¼d. last year. The locomotive expenses are 6·22d., against 7·1d. in the corresponding period of 1892. As I have explained before, we have to pay for the carriage of our coal, whereas the large railways do not charge for this item; and if you deduct this charge in our case, it brings the locomotive expenses to about 5d. per train mile, or very little more than what it costs in steam in the big lines; but our trains are much lighter than theirs. The receipt per passenger was 1·65d., against 1·60d. last half-year, showing a slight increase. The question has been raised whether we should not have taken something further out of our balance brought forward, and have paid another ⅛ per cent. dividend. We, however, thought, on the whole, that it would add to the general value of the property of the Company if we showed the greatest prudence in all these matters, and that rather than take from the balance brought forward we should add to it. That, however, is a matter of opinion. I may say now, in conclusion, as far as the working of the line is concerned, that we have now been open for three years, and I think we have shown that the electrical system is specially adapted to this class of traffic. I think it is pretty clear now that electricity, certainly for metropolitan railways, is going to be and is a cheaper mode than that of steam. Of course, in the early stages of the Company, there were many doubts expressed as to whether this system would be successful, but all those points are now beyond dispute. We have proved beyond all doubt that the electrical system of working is, as far as can be known, for an undertaking of this kind, the cheapest and the best. The position of the Company is a very solid one; it wants only an increase to our dividend on the Ordinary shares to make us take rank as one of the first in the kingdom. Our Debenture stock and our Preference shares, I am satisfied, are as solid investments as any one can get in these days, and they ought to command as high a price as those of any railway in the country. The question of carrying out the extension to Islington is one which we are carefully considering, but we are not disposed to move in that matter until we can do it in such a way as to make us feel sure that any diminution in our dividend will be avoided during the time these works are being carried out. The moment they are open, as soon as we can get properly into the City, as we propose to do, you will, I have no doubt, see our dividend go up rapidly. The cost of working the extension will be a very small addition. I am satisfied that the receipts from this source will be very large, and that they will be earned at a very small additional cost; but at the same time we must proceed with this matter with t e greatest possible caution. We have therefore not brought any proposal before you to-day in regard to this matter, and we shall not do so until we can present a case which you will feel is unanswerable. I think these are all the remarks I have to make, but I shall be glad to hear any observations from the shareholders. I will now conclude by moving—

'*That the report and statement of accounts for the half-year ended December 31, 1893, now submitted to the meeting, be approved and adopted.*"

Mr. EDWIN TATE briefly expressed his pleasure at seconding the motion.

Mr. DRAKE said that he had been travelling on the line that morning and got into conversation with a passenger, who remarked that the line was a great success, although perhaps this gentleman was not a shareholder. He (the speaker) had freely criticised their undertaking in its early stages; but he had obtained further information on the subject, which had tended to modify the severity of his criticisms. The management had not yet made the concern a commercial success; but the practicability of this mode of conveyance had been clearly demonstrated. He felt very strongly that they had now turned the corner, so far as making the concern pay, and any further judicious extensions would unquestionably add to the convenience of the public, and would increase the Company's profit out of all proportion to the cost of such extensions. He felt very strongly that they would act wisely in further catering for the teeming population of South London, either by loop lines or small extensions.

Mr. BLACKWOOD referred to the prospectus regarding the prospects held out originally. He congratulated Mr. Drake on that gentleman's thankfulness for small mercies, but for his own part he thought that ⅝ per cent. compared very unfavourably with the 12 per cent. per annum which was the prospect held out to them in the prospectus. He thought that an effort should be made to increase the fares, so that they might get something like what they were entitled to charge. The Chairman had anticipated a question which he had been going to ask regarding their locomotive expenses, which, they had been informed, were 6·22d. per mile last year, whereas they were originally assured that the charge would be only 3d., or at the outside 3½d.

The CHAIRMAN: If no one else has anything to say I will reply to Mr Blackwood's observations. I myself, as he has done, have referred from time to time to the original prospectus, because I have been quite as much disappointed as he has been with the result; but so far from misleading the shareholders at these meetings I have always, I think, been complained of for not making my remarks a little more *couleur de rose*. The prospectus was issued in the dark entirely as to what the circumstances of a line like this would be. Existing facts were given, and deductions were simply drawn from them tentatively—deductions which any one could have drawn as well as the Directors. I do not, however, despair of even the 12 per cent. being yet realised on this line if the policy we are adopting, and intend to adopt, is followed; but it is a difficult operation to carry out a line of this kind. In the first place we had to get the working power—a new working power hitherto unknown—into thorough order; but having succeeded in that, our intention is now to try and steadily develop the traffic of this line. That we have done so is manifest from the fact that, although our dividends have been small, they have steadily and regularly increased every half-year until the present occasion. We have this half-year earned more than we did in the corresponding period of 1892, but we have thought it prudent not to pay any more, because we wished in many respects to strengthen the position of this line and to give the public confidence—and our shareholders also—that we were acting as prudently as possible, and we are also advised by our auditor as to the wisdom of this course. Mr. Blackwood says that

Digitized by Google

we stated that we could work this line at 3d. or 3½d. per train mile. That is perfectly true, but that charge was purely for the electrical power He forgets what was stated at the time, that that was the arrangement with the contractor, and so far from that price being exceeded, we are now working at less than that. We have not misled the shareholders in any way in that respect. The amount is less than 3d. or 3½d., but Mr. Blackwood quotes that sum as if it was intended to cover the whole of the locomotive expenses, whereas it did not cover the cost, for instance, of engine-drivers, besides many other things. He has also referred to the figures given in the prospectus in regard to the number of people who pass over London Bridge, but that includes a very large traffic from the London Bridge stations, and we are unable to take advantage of that traffic by making a station in connection with those railways, as they would not let us have such connection. They did not believe in us then, but they have since altered their opinion, and they are now willing to let us join them. We have gone for a Bill, therefore, to enable us to secure that traffic, which forms a very large portion of the immense traffic which goes over London Bridge. I have no doubt, in fact, that when we get that station we shall have a difficulty in dealing with the traffic, although we shall deal with it, because we shall apply for additional siding accommodation, and get rid of the heavy inclines that we now have. As I have said before, too, the calculations in the prospectus were all based on a much more rapid service than we have at present. We had no idea that circumstances at King William street would confine our traffic as they are doing. We are endeavouring to get rid of these difficulties, however, and we are doing our best really to carry out the very objects which Mr. Blackwood has in view. With respect to his remark about the rate per passenger, Mr. Blackwood has raised a question of the greatest importance. If we could increase our rate we should increase our net revenue very considerably. We have tried all kinds of experiments for the purpose of doing this; we have altered our fares from time to time, and they are now somewhat complex in consequence. We have carefully felt our way as regards the different classes of passengers we carry, and for different times of the day. We are always trying to raise our fares, and we have succeeded in doing so to some extent; but it is not quite so easy a matter to increase the fare per passenger as Mr. Blackwood supposes. Our rate per passenger is exactly the same—or as nearly as possible the same -that the Metropolitan and the District Companies, as well as the omnibuses, re eive; and therefore it seems as if metropolitan passengers can only be got at about the rate that is charged. Every attempt has been made by these railways and omnibuses to increase their fares, but they have had to reduce them. Mr. Blackwood says that we should look at the competition of the omnibuses with the District Railway. It is true that there is that competition, but we have competition also, and what is the result? The District Company are unable to pay a dividend on their Ordinary stock after 25 years' working, whereas, we, after the first year paid a dividend and have gone on doing so, and I trust that we shall continue to increase our dividend. I really think that you cannot say that the comparison is against us. I quite admit all that Mr. Blackwood has said about the original prospectus, but excepting the 12 per cent., I do not think there is anything in the prospectus which has not been verified. It is true that we have not been able to get the traffic to the extent then expected, because that calculation was made on the supposition that the mid-day traffic would be the same as the morning and evening traffic, and that has not been the case. Until we can get the line extended we must have our trains half empty during part of the day. I do not think any Board of Directors could have been more anxious or have given more earnest attention to this concern than we have done; and we shall continue to do our best for you, and to get as large a dividend as we can.

The resolution was then carried.

The CHAIRMAN subsequently proposed, and Mr. S. BARCLAY HEWARD seconded the payment of the Preference dividend, which was agreed to, as was also the dividend on the Ordinary stock, on the motion of the Chairman, seconded by Mr. Tate.

The retiring Directors, Mr. Sampson Hanbury and Mr. Heward, were afterwards re-elected to their seats at the Board, and Mr. James L. Oliver, the retiring auditor, was re-appointed.

On the motion of Mr. DRAKE, seconded by Mr. BLACKWOOD, a cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN acknowledged the compliment, remarking that the Directors might have made mistakes, but their earnest desire had been to carry on the undertaking honestly and remuneratively. Such votes of thanks went far to encourage the Directors to increase their exertions, if possible.

The proceedings then terminated.

Eastern Telegraph Company (Limited).

The forty-third half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, January 25, 1894, at Winchester House, 50, Old Broad-street, London, "to receive the Directors' report and accounts, elect Directors and Auditors, and transact the ordinary business of the Company." The chair was taken by Sir John Pender, G.C.M.G., M.P., Chairman of the Company.

The SECRETARY (Mr. George Draper) read the notice convening the meeting; and the minutes of the last general meeting, held on Thursday, July 13, 1893, having been read and confirmed,

The CHAIRMAN said: Gentlemen, the report having been taken as read, before I ask you to adopt it, I shall, as usual, go over the working of the last six months, and give you such information as we ourselves possess, and which we think it desirable to be communicated to the body of the shareholders.

The gross revenue for the half-year under review amounts to £369,967, as against £352,391, or an increase of £17,576. Analysing the receipts from various sources we find an increase of £28,123 in the message receipts. There is an increase in the traffic with most of the different places, the principal being in the traffic with the Cape, India, and beyond. The total ordinary expenses for the half-year to September 30, 1893, amounted to £98,106, as against £98.797, or a decrease of £691. The details are as follows: general expenses in London £9,255, as against £9.120, or an increase of £135. The working expenses at stations were £75,707, as against £74.486, or an increase of £1,221. Several of the items under this head show substantial decreases, more particularly in travelling expenses, £509, expenses of land lines, and maintenance and renewals of electrical apparatus, &c., £298, repairs and renewals of furniture and fittings, £640. The principal increase is in the salaries and wages of our staff at stations, £2,439, there being an increase of thirty-two clerks compared with the corresponding period of last year. This, together with the operation of the scheme to provide regular promotion to deserving *employés*, which had been fully explained at previous meetings, accounts for the increase under this head. Comparing the other items in the revenue account, we find a reduction of £989 for special repairs to buildings at Alexandria, &c. The repairs being completed, this account is now closed.

I think I explained to you at a previous meeting that we have at Alexandria an important station, but the climate admits of a good deal of rapid destruction sometimes in the wood-work, so that we have had to make a regular overhaul, and introduce iron in many cases in the buildings; but we have now made them thoroughly complete and efficient, and I hope that we shall not be troubled again for a very long time. There is also a decrease of nearly £1,000 in the amount carried to maintenance ships' reserve fund. We carried as much to this account as in the previous half-year, but the difference has been subscribed by other companies hiring our ships from time to time.

The expense attending repairs and renewals of cables amounted to £31,906, as against £37,636, or a decrease of £5,730. It will be seen from Abstract C, page 6, that we have received during the half-year over £20,000 for the hire of our ships from cable companies associated with us to a considerable degree. We have also been fortunate in not having to expend so much cable in effecting repairs, so that although we have had five ships more or less busily employed during the half-year, the cost of maintaining communication has been less than for some years past.

After providing the usual amount for interest on debentures and debenture stock we are able to pay the usual interim dividend for the half-year at the rate of 5 per cent. per annum, and to carry forward the substantial sum of £86,252. I may inform you that this is, I believe, the largest amount we have ever carried forward. I think that is encouraging, and from what I have told you, I believe, you will feel satisfied that economies have been effected by us, and that the whole concern has been very closely and carefully watched. We have applied a further sum of £35.505 from the reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable and other expenditure, so that our capital expenditure on account of cables, land lines, &c., practically remains at the same figure as it did eight years ago. The total sum applied from the reserve fund from time to time now amounts to £1,292,000. This is a very large sum, gentlemen, and it would otherwise have been in the reserve fund, but it is practically working for the benefit of the Company. We have duplicated and triplicated our cables, we have not increased our capital, and as you will very well understand, we have, owing to these duplications, &c., and the large reserve fund which we still possess, placed the Company probably in as strong a position as it is possible for us to enjoy.

I have now put before you a statement which I think must satisfy you all. It is a very encouraging one, but it is one which has not been arrived at without great attention and care on the part of your staff and on the part of those who manage the staff. While the Directors do their work in this way—doing it well, I hope - we have at the same time been very modest in our demands for any increase of remuneration. On the death of our late Managing Director, a colleague of whom I spoke very warmly on the last occasion, we reconstructed to some extent the work of the management of the Company, and by the arrangements then made, we have, I think, given great efficiency and strengthened our position in every way. Nevertheless, what we have done only entails on the Company something like £300 extra. This is a very small sum, as you see, particularly as, I think, the efficiency of the Company has been maintained and strengthened by what we have done. I may also state that if we had claimed what we were entitled to when we became Directors of this Company we might have asked you to approve of a very much larger sum being paid to us. For many years we have been discharging our duties for an amount at least £1,000 less per annum than the Directors are entitled to by the Articles of Association, but the time may come when those who are guiding this great undertaking and who are devoting the greater part of their time and their life to the work may ask you to approve of their receiving a larger amount of remuneration. At the same time I shall, I hope, be in a position to justify any request of this nature, because we shall never ask you for anything further unless we improved the position of the shareholders at the same time.

You will find on reference to paragraph 5 of the report that the cable connecting Lisbon and this Company's general system with the Islands of the Azores was laid and opened for traffic in August last. This Company has taken a large interest in that cable, but, as I told you before, the *quid pro quo* we have received is an extension of the exclusive rights which we have possessed for many years at Lisbon, that extension being for a period of ten years. I need not tell you that this is worth a very large sum to us, and by-and-by, in all probability, we may be able to add to the revenue of our Company through this extension.

The Company which is associated with us, the Eastern and South African Company, has laid the cable from Zanzibar to Seychelles and Mauritius. That matter was for a long time under negotiation, but the work has now been carried out, and the cable has been opened for traffic. The Eastern and

Digitized by Google

South African Company receive for that a subsidy of £28,000 a year, but we are practically the holders of all the stock in that Company, and this cable, therefore, benefits us to some extent. I can scarcely tell you much of the result of its working yet, but so far as it has gone it has not disappointed us, and I think by the next time I meet you I shall be able to give you a good account of the working of that system.

We have also effected, I think, an important saving in a change we are making now in the Levant. As you are aware, the Island of Zante has been of late years subjected to very violent volcanic eruptions, and it has been very fortunate that our station has so far been saved, but if another eruption occurs, our cables might be interrupted, and that would be a serious inconvenience to us. We have, therefore, decided to remove the work which has hitherto been done at Zante to the island of Syra, where we have an important station. We calculate upon effecting a saving there of £1,700 to £2,000 a-year, and I think with greater stability and security for the Company's general system. That work is just being carried out, and I hope that by the time I address you again, if I am spared to do so, I shall be able to congratulate you on this having been a successful change.

I have now gone through the details generally, but before I sit down I may just mention again that the work which at the last two or three meetings I have told you was in hand has all been successfully carried out. It has all added to our general system—our great system, I now call it; and it has, I think, strengthened it. I believe that it will also help us to maintain the very good and sound and very proud position we occupy at the present time. Telegraphy must go on; it is impossible to stop it. I think that the business world would almost come to an end if the submarine telegraph companies, which unite the whole of the world together so closely, were to be stopped, or if their work were in any way interrupted. It will be our business to prevent interruptions. It will be our business to strengthen the system as much as we can and to connect it wherever the British flag flies. Wherever British commerce can show us that it will be a benefit to us to be connected with it, we shall make a great effort to attain this purpose. We have succeeded so far in connecting almost every part of the civilised world with our system. Some one said to me the other day that we shall be going to the moon next. (Laughter). I do not know that we shall do that, but if any part of the globe requires telegraphic communication, and can afford to pay for it, you may depend upon it that we shall see if it can be given. One is very apt to become a little egotistical in addressing a body of intelligent shareholders as to the work that has been done, but if you will allow me, I should like to say a few words on this subject. I have before remarked that our existence has been a comparatively short one. We have not yet been 25 years in existence, but we have done an enormous amount of work, the value of which is best tested by the opinion the investing public hold concerning it. I think I told you before that the debentures which have been issued by this Company stand remarkably well in the market, and to-day they are worth about £116 for the £100 debenture bearing 4 per cent. interest. I cannot give you any better idea of the opinion which the investing public hold of the position of the Eastern Telegraph Company. (Applause.)

I have given you, so far, a very rosy description of our position, but like other people we have a skeleton in our cupboard. We have the difficulties of exchange. The silver question has engaged the attention of some of the best heads and strongest brains that we know of, but as far as I can see they have rather made a mess of it as yet. They have given us no solution of the question, at any rate. This is a matter which very materially affects the remittances we receive from abroad. I am not going to tell you what we lose by it, because I have shown you that we have secured a very good result independently of these losses, but nevertheless our losses by exchange at the present time are very serious indeed. We try to meet them and remedy them by getting the countries where we lose by the exchange to allow us to increase our rates, but we can never do this to such an extent as to cover the loss which we sustain. We have to bear in mind many questions in connection with this subject. We have to see that people who employ the telegraph to such an extent as they do are fairly dealt with, and that while giving a thoroughly efficient service we do not exact too much from those who use it. We have these difficulties, however, and we do meet them to a certain extent. At all events, as long as I can come before you and present you with such a satisfactory account as I have done to-day, I think you will generally agree with us on this side of the table that we are doing fairly well, and nothing will please us more than to find that our shareholders are satisfied with their position—the shareholders who have stood by us and taken a part with us in building up the submarine system of telegraphy. I think that they must all feel satisfied that their investment has been not only a good one—useful to the commerce of the world—but for themselves a very satisfactory one also. With these remarks, gentlemen, I now beg to move the following resolution:

"That the report and accounts of the Directors to September 30, 1893, submitted to this meeting, be and are hereby received and adopted."

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: If any gentleman has any question to put to me, I shall be very glad to hear him before I submit the resolution to the meeting.

Mr. BAINES: Before the resolution is put I should like to make a few remarks. We have met here very frequently, and we see that a very large sum is carried to the reserve fund. A good deal of this money has been used to duplicate and triplicate the cables. This has added to the value of our property, and has enabled you to present to the shareholders very excellent reports, but I notice at the same time that the dividend paid to the shareholders never improves very much. It has occurred to me that it may be well worth their while if the Chairman and his co-Directors will consider the desirability of giving the shareholders something to represent the large sum which has been diverted from their pockets in the way of dividend and apply this *pro rata* to their holding. You might make an issue to us in the shape of shares, and we should then be able to go and get the benefit if we chose to sell. This property has increased in value, but there is nothing to represent it. We never get very far beyond 6½ per cent., and in the early days of the establishment of the Company, the prospect of very different results was held out to the shareholders. These results have not been realised owing to various causes which the Directors could not very well have foreseen, but I think that the time has come when the Chairman and his co-Directors might in this way consider the interests of the shareholders. I was very glad to gather from what the Chairman said that their interests were being considered. The increased remuneration referred to by the Chairman is very small indeed, but I hope he will not forget the shareholders. There is one question which I should like to ask before I sit down, and that is whether, in the event of war, our cables are in any way neutralised.

Mr. JOHN NEWTON: Before you answer the question I should like to say a few words. Twenty years ago if you had proposed even such a modest increase to the Directors' remuneration as you have mentioned, I should have got up and probably opposed it very strongly. I daresay you think that that is quite my character. (Laughter.) I think it is only right, however, having had since then 20 years' experience of what the Directors have accomplished, that I should say that I heartily agree with the proposal, and I think, if anything, that its modesty is its fault, especially when we look around us, and see, for instance, what certain other Directors, who are connected with this building, have done for their shareholders, and then when we look at the reserve fund of this Company and see the character of the investments which have been made by our Directors. With respect to the suggestion which has been made as to issuing anything to represent the reserve fund, I think it is very well represented, and in the very best manner you can possibly have it. You have a reserve fund of a substantial sum, but it is represented in the market by something like £2,000,000, and I think the property of the shareholders is substantially represented by that sum. That is an addition to our property, and it results from the satisfactory dividends which have been paid to us. I think it is due to the Directors that I should make these remarks, knowing what has happened in the past, and that they have done so well for the shareholders as they have. I certainly think that the increased remuneration that has been mentioned will not be objected to by any of the shareholders. In the early days that I have alluded to our shares stood at something like 7½ or 8½, and I may say that I am interested in them at those prices.

The CHAIRMAN: If no other gentleman has anything to say I will now reply to the remarks that have been made. In the first place, I may say to Mr. Baines that our legal adviser tells me that his proposition is illegal, and we may, therefore, drop it on that account. It could not be carried out. In the next place, let me say this: While big dividends are very desirable on the part of the shareholders, who all want large returns, we are working a system respecting which we have yet much to learn. It is not like a railway. You can see a railway; you know how it is working, and how the depreciation is going on, but we cannot say so much yet with respect to submarine cables. It is, therefore, wise in your interests, and prudent on our part, so to increase our reserve fund that we shall not be placed in the position, if we require to renew a cable, of not having the means to do it with. It is with companies as with individuals—the bigger your account is at your bank, the richer a man is; in a time of trouble the more he is valued. We are valued because we do our work extremely well, and because we have paid a very fair and steady dividend all through. We do not want to make other people envious, and so excite competition. We have created a very powerful Company, and we have added to the value of your shares. Since the time that Mr. Newton refers to we have doubled their value, in fact, and you cannot have double the value of your shares and at the same time increased dividends. We are now paying you a steady 5 per cent. dividend, and at the end of the year we give you a bonus, which at that time we determine on. This is not the time when we deal with that question, but at the end of the year we shall, as usual, deal with it. We have heretofore given you a bonus of 1½ per cent., and I think that we can continue that, and I shall be delighted if we find that at the end of the year we can with prudence increase the bonus, and I do not mean to say that we shall not do so. We have, as I have told you, duplicated and triplicated our cables. We have thus added to the value of your property to a very large extent, and to an extent which we could not have done if we had divided the whole of our income in dividend.

Mr. BAINES: I suppose that I am not entitled to reply?

The CHAIRMAN: I think not. I think that you had better come here six months hence, when we shall be very pleased to hear you again, but I now wish to answer the question which you have put to me, as to how our cables stand in time of war. I will tell you a little story, affording the best illustration which I can give you of the position you occupy. Many years ago I mentioned to a gentleman holding a confidential and very high position at the Foreign Office, "We are laying these cables, which are costing us a great deal of money. Would you agree to sign a document getting the nations of Europe—the nations of the world, I may say—to neutralise our cables in time of war?" His reply was, "I will sign it to-morrow, but the general in command on the spot, or the naval commander, would break it if a war were to occur." There it is, and the whole thing depends upon the action of the cables at the time. I only hope that they will not be destroyed either by the military or naval commander. Still, they have the power to enter our offices and shut them up, but I trust that they won't destroy the cables. War does not continue now so long. I think that the cables will be used to a very great extent either in war time or peace, but they are made for peace. When, however, they are used for the purposes of war, they will be employed by the power which has the greatest opportunity of dealing with them. I think I have now answered all the questions, and I will

Digitized by Google

therefore ask you to vote. Those in favour of the resolution will please hold up their hands. To the contrary. Carried unanimously.

The VICE-CHAIRMAN (Lord Tweeddale): Gentlemen, the next motion is as follows:—

"*That Sir John Pender, G.C.M.G., M.P., who now retires, be and is hereby re-elected a Director of the Company.*"

Sir John Pender, as you are all aware, has devoted his great abilities, and the whole of his time to the direction of this Company and other allied telegraph companies, and with what success you are the best judges. Probably there are no more successful companies in existence than these telegraph companies, and that success is due in a very great measure to your Chairman. I therefore move this resolution with the utmost pleasure, and I believe that it will receive the unanimous approval of all who are present.

Mr. GEORGE GARDEN NICOL: I have the greatest pleasure in seconding the motion, and in endorsing all that has been said by Lord Tweeddale.

The VICE-CHAIRMAN put the motion in the usual way, and it was carried unanimously.

The CHAIRMAN: I thank you, gentlemen, for this renewed mark of your confidence in your Chairman. Every man has his hobby. I have made submarine telegraphy to a great extent my hobby. I do not hunt, I do not shoot, I do a little bit of yachting; but the greatest pleasure of my life is to attend to the interests and the duties devolving on me as your Chairman. I thank you again for your renewed confidence in me. I have now to move—

"*That Charles W. Stronge, Esq., C.B., who now retires, be and is hereby re-elected a Director of the Company.*"

As you are aware, Mr. Stronge has had to do with us, more or less, during the whole period of our existence. Mr. Stronge, as you know, was a high official at the Treasury. We had to make hard bargains with him sometimes, but he was so just, so generous, and took such an interest in the work, and knew it so well over so many years, that we thought it would only be a proper compliment to him, and at the same time a great benefit to the shareholders, if we asked him to take a seat at our Board. I have very great pleasure in asking you now to re-elect him.

Lord SACKVILLE A. CECIL: I beg to second that.

The CHAIRMAN put the resolution, which was carried unanimously.

Mr. STRONGE: I am much obliged to Sir John Pender for the handsome manner in which he has proposed my re-election, and to you, gentlemen, for the way you have responded. You may depend upon it that my best exertions will always be at the service of the Company.

Mr. JAMES GIBB: I beg to move—

"*That the firms of Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Welton, Jones and Co. be and are hereby re-elected auditors of the Company at a remuneration of £100 to each firm.*"

Capt. GOODSALL: I have great pleasure in seconding the resolution.

The CHAIRMAN, in putting the resolution to the meeting, said: Previously, as you are aware, we had independent members of one of these firms as auditors, but we thought it better that the firms themselves should become our auditors, because if one partner was ill another could act for him. I think, however, that I mentioned many years ago that our accounts are audited not merely every six months, but that there is a continual audit of our accounts being made by these gentlemen, so that they are really practically responsible to you. We do not dictate in any way to the auditors. They are the servants of the shareholders, not the servants of the Board, but we generally manage somehow or other to pull along in perfect harmony. We want nothing that is not right, and they want nothing that is not just and proper. The motion was then put, and having declared it carried unanimously, the Chairman said: I think that finishes the business of the day. As you are aware, this is an interim meeting, and I am only too happy to find that we have been able to present you with such a good statement.

Mr. BAINES: Perhaps, as I have put a question or two, I may be allowed to propose a vote of thanks to the Chairman and Directors of the Company for the way they have managed our affairs.

Mr. W. GRIFFITH: I am very happy to second the motion. We are indebted, I think, to the gentleman who has just spoken for introducing a very important point respecting the neutralisation of the cables in the time of war. Our very able Chairman I find has, however, considered that question; but I would suggest that there is one advantage to us from the neutralisation of our cables, even though the general in command might break them. In that case we should have a claim for damages if they were neutralised. I am connected with a society for promoting the amendment and the reform of the law of nations, and this matter has been considered both in connection with the Suez Canal and in connection with our cables. We cannot do away with all war, and it would be the duty of the commander in the neighbourhood of the cables to take possession of them; but if the nations of the earth consented to the neutralisation of this valuable property we should have a claim for any damage that was done. That, however, is by the way. The very interesting statement made by our Chairman is most satisfactory, and shows that our prosperity continues and is likely to continue. It seems, as far as human fallibility can prognosticate things, that we shall have a prosperous future, and I think that we are greatly indebted to those who have brought about this position. It is only a proper mark of our gratitude that we should return our thanks to our Chairman and his able colleagues for what they have done for us in the last six months.

The motion was put to the meeting and carried unanimously.

The CHAIRMAN: Gentlemen, nothing pleases me more than to find that the shareholders appreciate the work of the Directors. When I look back to our early times and remember the remarks that were then made, and look at our present and improved position, I am glad to find that those who used to hit us very hard at one time come here to-day and approve generally of what we have done. I do not dislike criticism; I rather like it; but I am glad to see that you approve what we have done for you. We have got a very efficient staff. As you know, we have attended to the interests of the staff as much as we have attended to yours, because if you want work well done you must have good tools to do it with, and I can only say that we have the most perfect harmony throughout our system. The staff are very well pleased with what we have done for them with regard to their future; I refer to the pension fund. Altogether, gentlemen, the more you look into our affairs, the more you inquire into them, the more, I think, you will be satisfied that we have a machine which is working harmoniously in all its parts. As regards the Directors, I may say that we act upon this principle, gentlemen, that we must be just to those who are dealing with us, just to those who are working with us, and just to those who are dependent on us for their dividend. I hope that we shall continue to satisfy all interests, and maintain the successful position which we have enjoyed for so long.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of this Company was held at Winchester House, Old Broad-street, E.C., on the 26th inst., the Most Hon. the Marquis of Tweeddale presiding.

The SECRETARY (Mr. T. H. Wells) read the notice calling the meeting and the minutes of the previous meeting. The report of the Directors and statement of accounts were, as usual, taken as read.

The CHAIRMAN: Gentlemen,—The amount available for dividend this year is less by £13,893. This sum is made up of three principal items. The traffic receipts show a falling off of £8,493, and this time last year we had an item of £3,000 for the charter of our steamship "Minia," and at that period we transferred £1,619 from the interest of the renewal fund account to revenue, making altogether £13,112. This year there is a slight increase —not a very considerable one—in the expenses amounting to £622. You will have noticed, I daresay, from the accounts, that under abstracts "B" and "C," namely, expenses at head office and stations, there is a substantial reduction in the expenses. Against these decreases, however, there is an increase in the cost of repairs amounting to £2,194. The net result is, as you are aware, that the dividend is 13s. 6d., as against 17s. 6d. this time last year, and on the year £2. 11s., as against £2. 15s. The reduction of the receipts, it is hardly necessary to tell you, is due considerably to the dull trade which has prevailed for so many years, and which was very great during six months of last year. You can easily understand that it was impossible for us to recommend that any portion of the interest on the renewal fund should be applied to dividend, and the failure of our expedition to repair the two cables which were interrupted, and regarding which I warned you at the last time I met you, caused us to adopt this course. We regret very much the failure of those expeditions, which was mainly—I think that I may say exclusively—due to the bad weather that prevailed at the time. I may just give you an idea of how unfortunate we were in that respect by mentioning to you that the ship "Minia," which was employed in repairing the Brest-St. Pierre cable was 47 days out, being 36 on the spot, and the weather was unfavourable throughout. Thirteen dredges were made, and the cable was hooked 12 times, but owing to the badness of the weather no further progress could be made. In the case of the "Calabria," sent to repair the 1874 cable, she was out 100 days, 78 of which were spent on the ground, and seven only could be said to be calm and smooth. Fifty-one dredges were made, and the cable was hooked no less than 27 times. Now, with regard to the condition of these two cables, I am glad to say that the 1874 cable was found to be in a very good state, and we have no doubt whatever that it will be easily repairable when the time comes for sending out an expedition for that purpose. The Brest-St. Pierre cable, on the other hand, is by no means in the same condition. You all know how much trouble this cable has given us. We have not formed any opinion as to what steps should be taken to put it into proper condition. It will require a great deal of consideration, and we shall have first to obtain the opinions of the best experts in connection with the cable, and then we shall act accordingly. I am glad to be able to say also that both the Western Union Company's cables are in good order, the one which was interrupted the other day having been repaired. Having regard to the age of our cables, and to the possibility of one or more of them failing, as well as to the absolute necessity of providing means for carrying our large traffic as efficiently in the future as it has been done in the past, the Directors, after very careful consideration, have decided to lay a new cable of superior type and carrying capacity. This decision was not come to, as your report tells you, without due thought and consideration. The expenditure is a large one, but we felt that if we were to maintain our position in the Atlantic as carriers of traffic we were bound to see that we should have ample means at command for that purpose. Now, the cost of this cable will be £450,000, which, I think, will be regarded by you as moderate, and as a great deal cheaper than any other cable laid in the Atlantic, having regard to its quality and carrying power of 45 words a minute, which is better than anything yet laid, either in the West or in the East. Then there will be a sum of £5,000 or £6,000 required, partly to duplex this cable and to repair the duplex portions of the other cables which have fallen into disrepair. The expenditure on this cable will naturally reduce considerably our renewal fund, although it must be borne in mind that the renewal fund, as it stands, is for the very purpose of doing what we are going to do, namely, to renew our cables when they fall into a condition to require it. We should have been very glad if we could have delayed a little longer the time when we considered it necessary to lay a new cable; but we came to the conclusion that it would be imprudent, having regard to the age of the cable, to delay this

Digitized by Google

any longer. If all the facts in connection with the laying of a cable were as well known as those connected with a railway or any other undertaking of that kind, we should have no difficulty in telling you exactly how much money on account of depreciation should be put to reserve fund, but we have no reliable data to go upon. Therefore I think that you will agree with me that the proper mode of dealing with this is to deal with it at the close of each half-year, as circumstances appear to require. We recognise the necessity of not only maintaining the cables in good order, but of providing the means of renewing them when required, and in pursuance of this view and policy it is incumbent on us that we should lay by every half-year, or every year, a substantial sum to renewal fund. Without saying very definitely what will be done at the end of the half-year—it would be impossible to do so—I do not think that you can expect that we can recommend the laying by of a less sum than, say, £40,000 or £50,000, inclusive of the interest on the renewal fund as it exists. Assuming the interest were £16,000, and it would naturally increase every year, as the fund increased, that would require, on the basis of £40,000, something like £24,000 from the revenue account. Of course, if we thought it necessary to put aside £50,000, that would be about £10,000 more. What I want to point out is this, that we recommend that the renewal fund should be increased by a substantial sum each year, and that the exact amount should depend on the circumstances of each half-year. I think I have said enough on that subject, and you will understand exactly the policy I have indicated. With regard to the French lawsuit, I am able to say now, I think with some confidence, that it will be settled in the course of the next month. Well, we have reason to believe that it really will be settled—at any rate, as far as the particular Court in which it is at present is concerned. The only other subject I have to refer to is the death of Mr. Henry Weaver. That gentleman, as you know, was connected with telegraphy from its very early days. He was Managing Director of this Company for twenty-three years. He was a man of great ability, of great energy, and of great vigour of mind, and he devoted the whole of his time to the interests of the Company. He earned the respect of every person who came in contact with him, not only on this side of the Atlantic but on the other as well. We consider that we have sustained a very severe loss through his death. In conclusion, gentlemen, I am afraid that I cannot say that the year has opened very auspiciously. The turning in the proverbial lane does not appear to have been arrived at as yet in commercial circles. There is an improvement in some quarters, and we can only hope that this improvement will go on rapidly, and that when I have the opportunity of meeting you again six months hence we shall be able to give you a better account of our affairs than I have been able to do to-day. I beg to move—

"*That the report of the Directors and accompanying statement of accounts to the 31st December, 1893, submitted to this meeting be, and the same are hereby, received and adopted; and that the following dividends, as recommended by the Board, be now declared and paid, less income-tax—that is to say: (1) A final dividend of 13s. 6d. per cent. upon the Ordinary Consolidated Stock for the year ending 31st December, 1893, making—with £1. 17s. 6d. per cent. interim dividend already declared and paid by the Board by way of dividend on account—a total dividend for the said year of £2. 11s. per cent. on the said stock; (2) a final dividend of £1. 7s. per cent. on the Preferred Ordinary Stock for the year ending 31st December, 1893, making, with £3. 15s. per cent. interim dividend already declared and paid by the Board by way of dividend on account, a total dividend for the said year of £5. 2s. per cent. on the said stock.*"

The DEPUTY CHAIRMAN (Mr. Francis A. Bevan) seconded the motion.

Mr. GARDNER said that he was not quite so sanguine as the noble Chairman as to the largeness of the renewal fund being a criterion of a good price for a company's stock in the market. He was under the impression, moreover, that it was decided some years previously that a new line would not be laid without first consulting the shareholders. He was of opinion that a small reserve fund was better in their case at any rate, because when there was a large amount of money on hand there was a temptation to fall back upon it and lay a new cable where no cable was required. He advocated first the examination of the two existing cables to see if they were not amenable to being repaired.

Mr. BOURNE said that if the Directors had taken the advice which he tendered years ago they would have abandoned the Brest St. Pierre cable altogether. The repairs on that cable alone had already cost more than £450,000. He wished to know why the Company should have branch offices in different parts of the City, incurring an immense expense by way of rent, &c.

Mr. SEELEY said that they had arrived at this position, that, being once a most successful Company—he had been a shareholder from the time when they received 12 per cent. dividend—they had dwindled down and down till they had got below the price of Consols as a dividend-earning concern. They had amalgamated and "pooled" with different companies, but in all their arrangements, by some peculiar process, the Anglo-American Company had always got the worst of the bargain. He suggested, therefore, that they should alter their existing agreements with the various companies, with a view to improve their own position. He thought that they had made particularly bad bargains.

The CHAIRMAN: With whom?

Mr. SEELEY: With all the companies that you have ever amalgamated with.

The CHAIRMAN: I wish Sir John Pender were here, for he could tell you a very different story.

Mr. GOODSALL quite agreed with the Board in the desirability of laying a new cable, and expressed his opinion, as an old hand at submarine-cable work, that there were several cables which might be recovered with very little difficulty. Cables could be recovered at any depth with care.

Mr. GRIFFITH said that Sir John Pender, who was undoubtedly a great authority on telegraphs, said at the meeting of the Direct Company, that there were more cables for carrying messages at the bottom of the sea than were wanted, and that if they put more cables down these would diminish the value of those already existing. The Telegraph Construction and Maintenance Company was not the only manufacturing company of sub-marine cables. There were others in the field, and the terms on which they did business were that the manufacturing company received a certain rent every year for so many years—until such time as the cable was paid off, when it became the sole property of the company for which it was made. He ventured to put forward the suggestion whether some such policy should not be adopted in the case of the Anglo-American Company.

After a few remarks from Mr. FRY, Mr. CLARKE, Mr. GLOVER, Mr. BRADFORD and Mr. JOHN NEWTON,

The CHAIRMAN, in reply, said: I shall endeavour briefly to answer some of the questions. Mr. Gardner seemed to think that we take a pleasure in laying new cables. It is perfectly true that there are already more than sufficient cables to carry the traffic; but let me remind Mr. Gardner that the initial cables were not laid by us, but by other people who were perfectly entitled to lay out their money in laying cables if they chose to do so. The difficulty that we have always had in the Atlantic was that there were others laying cables there. There was first the French Company, then came the Direct, then the two American cables, and the Bennet and other lines. We could not prevent these from being laid; we could not prevent them from taking traffic. That was the difficulty. That makes ours about the most speculative stock that you could imagine. There is nothing to prevent anybody else in America from laying another cable. It is not our fault. With regard to the Brest cable, it is in a very indifferent state, and it will be a difficult question how we are to deal with it. With regard to the branch offices I must remind you that it is impossible to do without them. On the contrary, we find that the establishing of offices in every instance brings more traffic than the office costs. It is very remarkable that with both the Eastern and Atlantic Companies the more centres they have the more the public want them. I want to point out to Mr. Seeley that there have been as many as three cables out of working order at one time, which points very strongly to the necessity of maintaining our system in efficient order and laying a new cable. In reply to Mr. Goodsall I have only to say that you may be quite sure that every endeavour will be made to find the best place in which to lay the cable. We shall lay it in a position which will render it safe for probably a great many years to come. Mr. Griffith made one or two suggestions as to the way in which the renewal fund was being dealt with by the Direct Company. As that gentleman has referred to that, I should like to point out to him that the Direct Company's renewal fund is far from sufficient to renew their cable when it comes to be renewed. He suggested that something should be done, as was the case with the Cuba lines. These, however, are short lengths, and laid in shallows seas, and I can understand that a Company might be got to undertake to keep them in order; but I should like to see any company which would undertake to keep the Atlantic cables in order on the same terms. Mr. Griffith suggested that it was in the interest of the Construction Company to get more cables laid, but I do not think that you need be in the least afraid that we shall be guided by them in the future. In reply to Mr. Fry, who spoke from the point of view of a Deferred shareholder, I have to say that what is good for the holder of the Ordinary stock must be good for the other two. As to the amount of the renewal fund, I endeavoured to make that as clear as possible. We believe that something like £40,000 or £50,000 will be required every year. When this perfectly new cable is constructed in the very best possible manner and laid in the safest part of the Atlantic I think we may confidently regard the amount invested in that as if it were invested in the renewal fund. It is fair to consider it for three or four, or even five, years as a substantial part of our renewal fund, so that we shall be able to build up an amount gradually and sufficient for that. Mr. Clarke thought that we should have taken the shareholders into our confidence. Well, some of them are. Among others I represent a million and a-half of stock in the Anglo-American Company, and I am alive to my responsibility in connection with that sum. Mr. Glover seemed to think that we did not take sufficient pains to get as cheap a cable as possible. I believe that it is recognised by those who are acquainted with the price of cables that this cable is a very cheap one. Our engineers tell us that its price is very substantially less than the estimate formed by them (and they are very competent men)—in fact, something like £30,000 less.

Mr. GLOVER: Why was it not put up for tender?

The CHAIRMAN: We have been connected with the Telegraph Construction and Maintenance Company since the formation of our Company, and we have found that they have done our work admirably. It is a responsible Company with a large capital, and we feel safe in their hands. But if you suppose that we give to that Company always what they ask you make an entire mistake. We take ample means of ascertaining what should be the reasonable price for a cable, and that is what we did in this case.

The resolution was then put, and carried unanimously.

The CHAIRMAN moved, and Mr. BEVAN seconded, the re-election of Sir Albert J. Leppoc Cappel to his seat at the Board.

The motion was agreed to *nem. con.*

The CHAIRMAN next moved the re-election of Mr. Samuel Barber, the other retiring Director.

Mr. BURT seconded the motion, which was also carried unanimously.

On the motion of Mr. JOHN NEWTON, seconded by a SHAREHOLDER, the auditors, Messrs. Joshua Dean and John Caine, F.C.A., were reappointed.

Mr. GARDNER proposed, and Mr. BOURNE seconded, a vote of thanks to the Chairman and Directors, which having been cordially passed,

The CHAIRMAN expressed his acknowledgment, and the proceedings ended.

St. James' and Pall Mall Electric Light Company (Limited).

The ordinary meeting of this Company was held at the Offices, Carnaby-street, Golden-square, W., on Tuesday last, Mr. Eustace J. A. Balfour presiding.

The GENERAL MANAGER and SECRETARY (Mr. Frederic J. Walker) read the notice calling the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN proposed—

"*That the report and accounts of the year ending December 31, 1893, as submitted by the Directors be received and adopted, and that the dividends recommended therein be declared and paid on February 7th.*"

He said: Gentlemen, in moving the adoption of the report and accounts I am anxious to give the shareholders full information on the various points raised, as well as some facts which bear on the prospects of the company for the coming year. It is a matter of great regret that it is impossible to pay a dividend of more than 4½ per cent. on the Ordinary shares. The following are, however, the chief causes which have led to this state of things. The year has been peculiarly free from fogs. The ordinary citizen, when he wakes up in the morning and sees the atmosphere in the street of the colour of thick pea soup, certainly does not regard life from a more cheerful point of view. But the Electric Light Director, who has the interests of his shareholders at heart, pays no attention to his personal discomfit, as he realises that the day's earnings of his company will increase about 50 per cent. The peculiarly aggravating part of this year has been that some of the few fogs we have had have come on Sundays, when they are equally unpleasant, and do us but little good. Another cause is the increase in our parish rating by about £570. The amount we shall now have to pay to the parish is equal to about 8½ per cent. of the sum available for distribution in dividends. The chief cause has, however, been the lowering of our charges, forced upon us by the competition of the London Electric Supply Corporation. In this connection I cannot help referring the shareholders to the speech made by the Chairman of that Company in May last, in which he referred to the position occupied by the London Supply Companies in regard to their tariffs, and the reduction in the price per unit of supply. I was so astonished at his remarks that I inquired if the report was correct. The correctness of the report has not been denied, and the statement has not been withdrawn. In justification of ourselves, therefore, I am bound to say that, so far as this Company is concerned, Mr. Forbes was misinformed. It was only with great reluctance, and because our customers threatened to leave us and go to the London Company, whose charges had already been reduced, that we consented to lower our rates. We dislike this policy, but we have no choice. Perhaps a time will come when the London Company will look at the matter as we do. If this happy result were to occur, and if we can diminish in the coming year our law charges, as we hope to do, we ought to be able largely to increase the sum available for distribution among the shareholders. Another cause is the increased economy shown by consumers, especially those on a large scale. There are many satisfactory features in our year's working, which show that the business of the Company is on a sound basis. The number of lamps wired has increased by 25 per cent. At the same time the cost of production has sensibly diminished, and the Directors will use every endeavour to maintain and possibly to increase this economy of working and management. The Directors regret that, contrary to anticipation, they have been obliged to exceed the estimated capital expenditure by about £11,000. This is due to the absolute necessity they were under, of purchasing additional properties in contact with this station, and further to the necessity of increasing the output of this station by putting down additional boilers and machinery. This is of course in itself a satisfactory feature. The remainder is accounted for by the charges in connection with the Hopkinson patent. The working of the system has been very satisfactory, and the Directors have every reason to believe that their customers as a whole are thoroughly satisfied with the light furnished to them. Finally, I wish again this year to take the opportunity of thanking our staff for the energy and ability with which they have assisted us in carrying on the business of the Company. Mr. Dobson, our chief engineer was unfortunately taken seriously ill in July last, and although happily much better, is still abroad. His place has however been ably taken by Mr. Andrews and Mr. Leach, in which they have been assisted by the special engineering knowledge of the Secretary, who has added this to his ordinary labours.

Mr. LATIMER CLARK seconded the motion.

Mr. DAVISON thought that they ought not to allow the present opportunity to pass without expressing their disapproval of the cost of management of this Company. The return of 4½ per cent. for the whole year on the Ordinary shares, less income-tax, was a very poor dividend for the money invested. The cause of the present state of affairs appeared to arise from keen competition and very heavy expenditure. He considered that it was the duty of the Directors to lessen that expenditure. He thought that the shareholders would agree with him, that strict economy should be exercised to produce the favourable result which was expected on the formation of the Company.

Mr. WILLIAMS said that he had three questions to ask, namely, why it was that the Company acted in conjunction with the low tension supply companies in resisting Dr. Hopkinson's claim when the unsuccessful result showed that they were not justified in doing so, and by whom were they principally advised to litigate this claim? What was the proportion of the sum of £4,446 attributable to law expenses, and did the proportion include the costs of the company's solicitor in that unsuccessful litigation? If it did not, had the Company's solicitors' costs been delivered, and what was the amount? The Judges having expressed the opinion that the claim of the holders of Founders' shares was clear, notwithstanding that it would have been desirable to have provided for following another policy, was that claim protested, and heavy law costs incurred?

Mr. F. BOURN said that he understood at a former meeting that the question of the Founders' shares was to be referred to arbitration. He thought the cost of the action for the infringement of the patent should have been spread over several years.

Mr. SAMS said that he saw they were about to increase their premises. Was it because they had such an immense business that it could not be managed at Mason's-yard and Carnaby-street?

Mr. A. TOOTH said that under the circumstances of the litigation he wished to know whether since the drop in the price of the shares the Directors had unloaded their holding.

Mr. LIBERTY, referring to the cost of the legal action, asked on what grounds it was carried to capital instead of being shown, as he submitted it was, as a real loss during the current year. If it was not a loss in the current year, why should not some such hypothetical sum have been added to capital account in former years on similar grounds? He noticed that the reserve capital fund had been invested in other securities bearing a larger rate of interest. Did that circumstance carry with it any larger risk? He was very pleased to bear testimony to the very efficient manner in which the work of the Company was performed. The question of the Directors' remuneration ought to receive their careful consideration. Why was it suggested to add another member to the Board?

Col. FRANCIS could not congratulate the Directors on the straightforwardness of their statement on the actual position of the Company. There had been litigation on three important points. He firmly believed that Dr. Hopkinson had no antagonistic feeling to the Company, and that that gentleman, if he had been met in a straightforward manner, would have let the Company use his patent for a small remuneration. If they looked to last year's account they would find that £659 was put to expense account for the costs in connection with the action, so that the whole outlay on that unfortunate business had been £5,105. Coming to the Founders' shares, these, he said, were selling in 1891 in the open market for £350 each, the last one being sold to his knowledge by a Director of the Company for £365, and it was important that the shareholders should know that the litigation connected with these shares had been forced upon them by the action of the Board. The case had been several times dismissed without a reply, showing that there never really was one for them to go to law about. He was deeply sorry to tell them that if there was anything more calculated to injure the Company and ruin its prospects than another, it was the settlement enforced on the directors by the Windham Club. It had formerly been distinctly stated that the lighting capacity of this and the other station was framed for 100,000 lamps; their present supply was 58,000 lamps, and yet they were asked to enlarge their premises to carry on their work.

Mr. SCRASE said it would be interesting to know what had been paid for Dr. Hopkinson's patent rights, and what had gone in legal expenses. They had, he thought, acted *ultra vires* in transferring what should have been put to redemption fund into revenue account. Again, in 1892, when the machinery was smaller than it was now, they put depreciation at £3,500 odd, whereas now, when the machinery was larger, £1,292 was thought sufficient for the item. Reasonable business men naturally concluded that either the former sum was too much or the latter was too small. On what terms also was it proposed to issue Debenture stock?

The CHAIRMAN, in reply, said that the cost of management had decreased during the year under review. He did not think that there was another Company in London conducted at so small a proportion of outlay to receipts. The Directors' fees had slightly decreased per unit of light supplied since last year. He was certain that they were not extravagant. In reply to Mr. Williams as to the action brought by Dr. Hopkinson against the Company, he would merely repeat what the Directors stated in the report:—"They are happy to report that a compromise was effected on very favourable terms, under which the plaintiff waived his costs and granted a licence to the Company for the remaining term of the patent and any extension thereof. The cost of the licence and the proportion of law expenses attributable to this Company, amounting together to £4,446. 8s. 9d. is considerably less than the additional sum that would have been expended on the mains had the Hopkinson system not been adopted." It was also less than they should have had to pay for a licence, so that they were actually the gainers by having gone to law on the point. The owner of the patent was not Dr. Hopkinson, but the Westinghouse Company. The solicitor employed in the action was the solicitor of the joint companies, and not their own one. The cost of the action was practically equal to the purchase of the patent, and it was clearly capital expenditure. One of the directors only had unloaded 30 shares during the year, which was the only change. The investments were changed to get a larger interest. They proposed to add another member to the Board, but this would not involve a greater expense to the shareholders—the Directors individually would receive less. The Directors had not yet determined how to raise further capital, but the present proposal was to issue 4 per cent. Debenture Stock to the shareholders. It was not to the interests of the Company that he should enter into the settlement of the dispute with the Windham Club. No Director had sold Founders' Shares.

The report and accounts were then adopted.

The retiring Directors, Mr. Eustace Balfour and Mr. Latimer Clark, F.R.S., were, on the motion of Sir JOHN H. MORRIS, seconded by SHAREHOLDERS, re-elected to their seats at the Board.

The CHAIRMAN next proposed the election of Mr. Bennett Fitch, M.I.C.E., as a Director of the Company.

Mr. FRY seconded the motion, which was carried *nem. con.*

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., having been reappointed, a vote of thanks was passed to the Chairman and Directors, and the proceedings ended.

Crompton and Company (Limited).

An extraordinary general meeting of the above Company was held at the City Terminus Hotel, Cannon-street, E.C., on Tuesday last, for the purpose of considering, and, if approved, of passing the following resolution:—

"*That the Directors be, and they are hereby, authorised to borrow any sum or sums of money on such security and upon such terms as to interest or otherwise as they may deem fit, provided that the amount borrowed shall not exceed in the whole, without the further sanction of a general meeting of the Company, the sum of £100,000.*"

Viscount EMLYN presided, and said that he did not think he would have to detain the shareholders for any great length of time on that occasion, as the facts which he had to put before them were of a very simple nature, although there were matters of very great importance. The notice calling the meeting gave the proprietors information as to what the Board proposed to do, and it would be his duty on that occasion to direct their attention to three points. First of all, the views which the Board held that justified the proposed issue of debenture stock; secondly, the exact position of the shareholders in event of the issue being carried out; and thirdly, the inducements which the Board offered the shareholders to take up the issue. With regard to the first point—the merits of the proposed issue—the shareholders would remember that in the last balance-sheet laid before them there was a sum of £18,000 which the Company had borrowed from its bankers. Since that time, with a view of extending the business of the Company, and of enabling it to take up large contracts, the Directors had found themselves obliged to go to the bankers of the Company for more money, and he must say that looking to the fact that their bankers had the fullest possible information with regard to the Company, its transactions, and the accounts, it was most satisfactory to find that they were willing to make whatever advances the Board found necessary. The business of the Company was such that they were obliged to have a great deal of money locked up, as it were, when they were carrying out heavy contracts, and they had then to rely upon the consideration of their banking friends. At one time they might have a large sum paid to them, and then they were able to alter very materially the position of their account, so that the sum borrowed from the bankers was really a very fluctuating amount. It had been, however, higher than it was in the balance-sheet submitted in March, 1893. The Directors did not consider that that was a satisfactory state for the Company to be in, and they therefore asked the shareholders to sanction the additional capital in order to place it in a stronger position and enable it to deal with the business which he was sure would come, and was at the present time coming, in a very satisfactory manner. There were a good many companies with which they were doing business, and they had, therefore, a considerable amount of capital locked up. The Hove Company was one of these, and he believed that it had a great future before it. The work which they had done for that company represented a considerable sum of money. Then there was the Chelmsford Electric Lighting Company, which was another in connection with the same question. He thought that what he said at the last meeting had been amply justified. He said at that time that the prospects were that within a very short time the electric lighting of Chelmsford would be placed on a satisfactory and commercial footing, and he was now able to say that a provisional order had been obtained which would place the Company upon a business footing different to what it was in the past and in such a position that they would, he hoped, be able to liberate a considerable portion of their capital. There was another matter to which he alluded with regard to Australia, where he stated that he considered there were very good prospects, and he also said that within the last few months ended July last, the company had received more orders than they had obtained during the previous twelve months. He was glad to say that that state of things had continued, and that the Australian company was in a very satisfactory position. Within the last week that Company had taken a contract for £10,000. Their company had a large contract with the Great Eastern Railway, the Crystal Palace, a large contract at Antwerp and many others. The share holders knew that such large contracts could not be carried on without cash, and it was ready money that they required to enable them to take advantage of lower rates and discounts, and so enable them to carry on their contracts in a cheaper and better way. He need scarcely tell them what an immense advantage it was for a company doing contract work to be able to promise to pay cash, and so obtain a good discount and other facilities. As regarded the position of the shareholders, he would like to explain at once what that would be. What the Board proposed to do was to issue £100,000 Debentures, with which they would redeem the £50,000 Five per Cent. Debentures now issued, pay off the whole of the loan from the bankers, and free the Company altogether from those debts; in addition to which they would be able to deal with the trade creditors. As far as the trade creditors went, compared with the trade debtors, he thought the account was extremely satisfactory. They had only put down those they believed to be good debts, and they practically represented twice as much as the creditors. He thought that that was an answer to any shareholders who thought that the Board were putting a great deal before them. As regarded the interest, the Directors had worked it out as carefully as they were able, and they believed that the issue on the whole £100,000 would not cause an increase of more than between £500 and £600, and they felt sure that with the saving on the purchases for cash they would be able to make in the market they would cover that sum. With regard to that subject they were not speaking entirely prophetically, as they had some experience in the matter when the first issue of debentures was made. The next point he had to refer to was what inducements could be offered to the shareholders to take up the debentures. They had had up to the present time very fairly satisfactory returns, and they had no doubt that the whole amount would be raised on moderate terms. The inducement to subscribe was to bring the business into a firm, efficient, and satisfactory condition, and to enable them to accept large contracts and to carry out the works with more economy, to develop the business, and to ensure a better dividend than would be obtained otherwise. He thought that the loans which the bank had granted, acquainted as it was with the whole of the transactions of the Company, was a very good sign of the position of the undertaking. There was nothing which the Board wished to keep back from the shareholders with regard to the object of the meeting, as they were most anxious that they should have their full confidence and support. In conclusion the Chairman moved the resolution as above.

Mr. R. E. B. CROMPTON seconded the motion.

The CHAIRMAN, in reply to questions, said that the basis on which the valuation of the assets had been made was the value shown in the books and balance-sheets of the Company. The shares in other Companies stood at a value of £12,004 in the last balance-sheet, and at £12,375 in September. With regard to the interim dividend, he could not state what the Board would do if they got the whole of the £100,000 subscribed, but he might say, although he would not pledge himself on that matter, that they had every hope that they would be able to declare an interim dividend of 2s. 6d. per share within a reasonable time.

Mr. KITCHIN said that he and some of the other shareholders were of the opinion that the Company was in the habit of undertaking contracts and receiving its remuneration partly in shares and partly in cash. He considered that that was a very unsound policy, and if the £100,000 was to be issued for the purpose of continuing that policy he should have to oppose it. He did not consider it a business-like way of carrying on the operations of the Company.

The CHAIRMAM, in reply, said that he was of the same opinion as Mr. Kitchen, that the more business-like you could make a contract the better. He understood that when the contract for the Pretoria Company was taken some three or four years ago a certain number of shares were accepted representing a portion of the profit—not of money expended, but a portion of the profit on the transaction—but since then nothing of the kind had been done. With regard to the Hove contract, the Company had taken £2,000 in shares for the purpose of assisting that Company in its formation. They had a contract for £35,000 in Hove, the whole of which was payable in cash. It was his wish that that should always be done, although he could not pledge himself it always would be.

The resolution was then put to the meeting and carried, and the proceedings closed with a vote of thanks to the Chairman.

Brighton and Rottingdean Seashore Electric Tramway Company (Limited).

The first ordinary general meeting of this company was held at the Town Hall, Brighton, last week.

The CHAIRMAN made a statement with regard to the present position of the Company. The property they posessed was one which the Directors thought would prove to be very valuable. It was the first time that the Crown had consented to allow a long length of the foreshore to be used for a purely commercial undertaking. They had allowed piers to be run out seawards; but that was another matter altogether. They might think that the Directors had been rather tardy in getting to work, but he could assure them that in the face of many preliminary difficulties they had not lost any time. Their Bill was actually given up by their Parliamentary agents; but, by dint of perseverance and tact, they obtained the Act in the face of most serious opposition. They had settled the question of rental to be paid the Corporation for the part of the line within the borough and the station at Kemp Town, and all the necessary plans were virtually passed. The detail plans had also been passed by the Board of Trade. With regard to the practical aspect of the undertaking, the various points had been carefully considered by eminent engineers and experts on their behalf. The rails, which were of steel and of a heavy type, would be embedded in the solid rock with concrete, and this method of filling had been duly approved by the Government authorities. When the rails were covered by water to the maximum extent, a reasonable speed would be maintained; but when the water was low the speed would only be limited by the requirements of the Board of Trade. The cars would be very handsome, commodious, strongly built, and capable of carrying a large number of passengers, in fact, travelling drawing-rooms. They hoped to commence work early next month, and to complete the line in about six months, contracts having been entered into for the plant and material necessary to carrying out the undertaking. The undertaking was not started in the interests of any private adventurers, but by Brighton and Hove residents for the benefit of the town, with a hope of being recouped for their outlay by receiving a handsome dividend. Their nominal capital was £20,000, but after going carefully into the figures the Directors were of opinion that between £14,000 and £15,000 would be sufficient for the purposes of the Company, and this, he was delighted to tell them, had already been subscribed privately. No commissions had been paid for the sale of shares, nor had any expense been incurred beyond what was absolutely necessary. In fact, not a penny had been wasted. The time was rapidly approaching when the whole sea front from Rottingdean to Portslade would be lined with houses, and every method of conveying the population to and fro would be a mutual benefit both to the town and the driving interest. They firmly believed that this line would be a permanent and increasing attraction to Brighton. Its novelty, in that there was nothing like it in existence, would attract both scientists and engineers. Considerable interest would be aroused by it.

Messrs. E. G. Bleackley, J. J. Clark, Magnus Volk, and R. J. Pope were elected as Directors, and, in proposing the election of Mr. Volk as Managing Director, Mr. J. J. CLARK pointed out the great importance of the Company carrying out the construction of the line themselves in order to secure efficiency in the work. The Directors proposed, therefore, that

Digitized by Google

Mr. Volk should carry out the work for them, acting as Managing Director, and receiving remuneration for his work at the rate of 5 per cent. on the outlay. He was asked also to mention that, as Mr. Volk had assisted their engineer very considerably in the preparation of the plans and in getting them passed through Parliament, it had been arranged that he should receive 1 per cent. out of the engineer's remuneration. That was a perfectly straightforward, business-like arrangement, and was mentioned that everything might be above board. Mr. Volk would, of course, act as engineer in the electric work required, and receive the usual commission. He therefore moved "That Mr. Magnus Volk be appointed to superintend the construction of the line, and that his remuneration be at the rate of 5 per cent. on the cost of construction in addition to the 1 per cent. he is permitted to receive from the engineer to the Company for assistance rendered to him, and that Mr. Volk be paid the usual 5 per cent. commission on the cost of the electric work." That meant that the whole of their work would be carried out at a cost of 10 per cent. over and above the cost of material and labour.

After a brief discussion, the resolution was adopted.

Mr. J. G. Haslam and Mr. E. J. W. Sang were appointed auditors, and the meeting terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

T. CHESTERS AND SONS (LIMITED).—This Company has been registered with a capital of £4,000, divided into 200 Preference and 200 Ordinary shares, of £10 each, to carry on the business of bell-hanger, electrical engineer, &c., carried on by Thomas Chesters at Bootle.

EASTON, ANDERSON AND GOOLDEN (LIMITED).—This Company was registered on January 26th, with a capital of £200,000, divided into 10,000 £6 per Cent. Cumulative Preference and 10,000 Ordinary shares of £10 each, to acquire and take over as a going concern the undertaking of Easton and Anderson (Limited), and all or any of the assets and liabilities thereof, with a view to such acquisition to enter into and carry into effect an agreement with the said Company and its liquidators, and to carry on the business of civil, mechanical and general engineers, millwrights, shipbuilders, ordnance manufacturers, manufacturers of and dealers in mechanical, hydraulic, pneumatic or other apparatus, iron and brass, founders, smelters, wire drawers, galvanisers, electro-platers, metal workers smiths, metallurgists, manufacturing chemists, suppliers of electricity, cable and rope manufacturers, &c. The subscribers (with one share each) are Thomas P. Wilson, Frank S. Courtney, J. E. Compton-Bracebridge, Edward W. Anderson, Walter T. Goolden, Llewellyn B. Atkinson, and James R. Easton. The first Directors are T. Perceval Wilson, J. E. Compton-Bracebridge, Edward W. Anderson, Frank S. Courtney, Walter T. Goolden, and Llewellyn B. Atkinson.

MARINE STEAM TURBINE COMPANY (LIMITED).—This Company was registered on January 23rd, with a capital of £25,000, in £50 shares, to acquire certain patents and inventions relating to the construction, propulsion and equipment of vessels, with a view to such acquisition to enter into and carry into effect an agreement to be made with the Hon. Charles A. Parsons, of Newcastle-upon-Tyne, and to carry on the business of engineers, forgemen, shipbuilders and repairers, iron and steel manufacturers, electrical engineers, suppliers of electricity, &c. The subscribers are:—The Earl of Rosse (20 shares), Hon. Charles A. Parsons (20), Nathaniel G. Clayton (40), C. J. Leyland (40), John B. Simpson (20), A. A. C. Swinton (20), and Herbert C. Harvey (20). The first Directors are the Earl of Rosse, Hon. Charles A. Parsons, Nathaniel G. Clayton, Christopher J. Leyland, John B. Simpson, and A. A. Campbell Swinton.

MILDE TELEPHONES AND ELECTRIC SUPPLY COMPANY (LIMITED).—This Company was registered on January 29th, with a capital of £20,000, divided into 15,000 £7 per cent. Preference and 5,000 Deferred shares, of £1 each, to acquire, deal with, develop, and turn to account business concerns, letters patent, monopolies, licences, concessions, rights, and privileges relating to telephones, electric apparatus, and the like, to construct, maintain, lay down, carry out, work, sell, let on hire, and deal in telephone cables, wires, lines, stations, exchanges, reservoirs, accumulators, lamps, meters, engines, &c., to transact and facilitate the transmission of telephonic and telegraphic communications and messages, to undertake the lighting of towns, streets, buildings, and other places, and the supply of electricity for public and private purposes, and to carry on the business of a telephone, telegraph, and electric light, heat, and power supply company in all or any of its branches. The subscribers (with one share each) are:—Vaughan W. Jones, Quentin A. McConnell, William Milford, E. Duchamps, Egerton F. Hodge, L. D. Tottenham, and W. Saurin. The first Directors are to be appointed by the above subscribers.

ECONOMIC GOLD EXTRACTION COMPANY (LIMITED).—The annual return of this Company, made up to September 14, 1893, has just been filed. Out of a nominal capital of £175,000 in £1 shares, 139,880 have been taken up, of which 122,000 have been issued as fully-paid. Upon the remaining 17,880 shares a call of 17s. per share has been made, resulting in the payment of £14,410. 19s., leaving £802. 1s. in arrears, while £15 has been paid in respect of 120 forfeited shares.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The statutory return of this Company, made up to November 30, 1893, was filed on December 14th. But of a nominal capital of £400,000, divided into 150,000 Ordinary and 50,000 £7 per cent. Cumulative Preference shares of £2 each, 120,000 Ordinary and 12,845 Preference shares have been taken up, and all issued as fully-paid, in accordance with the terms of the agreement with the Electric Construction Corporation (Limited).

ELECTRICAL PLANT (LIMITED).—The annual return of this Company made up to December 26th, has been filed. Out of a nominal capital of £10,000 in £10 shares, 575 have been taken up, and 500 issued as fully paid. Upon the remaining 75 the full amount has been called and paid.

ELECTRICAL INSTALLATION COMPANY (LIMITED).—By special resolution passed October 19, 1893 (and recently filed), this Company raised its capital to £2,800, divided into 1,800 "A" and 1,000 "B" shares of £1 each, by the addition of 1,000 new "A" shares. The first annual return, made up to December 29th, has also been filed; the whole nominal capital of £2,800 was taken up, and the full amount called and paid thereon.

ELECTRIC METER COMPANY (LIMITED).—The annual return of this Company, made up to January 3rd, has been filed. The Company has a nominal capital of £50,000 in £10 shares, of which 2,007 have been taken up; 2,000 of these were issued as fully paid, and the full amount called on the remainder. The calls paid equal £30, while £40 is yet in arrears.

ELECTRICAL PURIFICATION ASSOCIATION (LIMITED).—The annual return of this Company, made up to and filed on December 30th last, shows that 18,326 shares of £1 each have been taken up out of a nominal capital of £25,000; 5,000 of these were issued as fully-paid, and the full amount called on the remaining 13,326 shares, resulting in the payment of £13,226, and leaving £100 unpaid.

LATIMER CLARK, MUIRHEAD AND CO. (LIMITED).—A notice filed on January 26th states that at an extraordinary general meeting held at 23, Regency-street, Westminster, S.W., on that date, the members resolved to wind up voluntarily, and appointed James Worley, of 27, Leadenhall-street, London, E.C., liquidator. The Company was registered on October 22, 1883, with a capital of £100,000, in £10 shares, to acquire and take over as a going concern the business of electrical engineers and telegraphic apparatus manufacturers, carried on by J. Latimer Clark and John Muirhead at 23, Regent street, Westminster, S.W. At the time of the last return in July, 4,709 shares were taken up, all of which, with the exception of the seven signatories' shares were issued as fully paid. The principal shareholders are John Muirhead (1,769), Francis L. and Henry J. Muirhead (1,350 jointly), and J. Latimer Clark (469).

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended January 28th, were £951, as against £976 for the corresponding period of last year, being a decrease of £25. The total receipts for the half-year amount to £3,839, as against £3,954 for the corresponding period of 1893, a decrease of £115.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—For the half-year just ended the Board recommends a distribution at the rate of 8 per cent. per annum.

FINANCIAL MOVEMENTS.—The following is from the *Financial Times*: "The past month has witnessed a fair business going in the shares of the leading Electric Light Supply Companies. The subjoined table shows the movements which have taken place. It is expected that the reports, which in most cases are about due, will show favourable results:—

Stock.	Price Jan. 2nd.	Price Jan. 22nd.	Rise.
Brush	2⅜— ⅝	2⅝— ⅞	¼
City of London	11¼— ¾	11¼— ¾	...
St. James's and Pall Mall	5½—6	6 — ½	½
Ditto Preference	7¾—8¼	8 — ½	¼
Westminster Supply	5 — ½	5¼— ¾	¼
Metropolitan Supply	7¾—8¼	8¼— ¾	½
Ditto Debentures	103 —6	104 —8	1½

INDIARUBBER, GUTTAPERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).—Subject to audit, the accounts to December 31st last show the following result:—Net profit for 1893, £94,605; brought forward from 1892, £46,845; total, £141,450; less interim dividend, £25,000—£116,450. The directors have resolved to add £50,000 to the reserve fund, and to recommend a further dividend of 5 per cent. (making 10 per cent. for 1893) and a bonus of 2½ per cent., carrying forward £28,950.

MACHINERY TRUST.—The Directors of this trust have declared an interim dividend to December 31st last, at the rate of 10 per cent. per annum, free of income tax.

ROBEY AND CO. (LIMITED).—Letters of allotment and regret for the issue of £125,000 Four-and-a-Quarter per Cent. First Mortgage Debentures in this Company have been posted.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ending January 26th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, (Limited), were £3,445.

YORKSHIRE BOILER INSURANCE AND STEAM USERS' COMPANY (LIMITED).—Mr. W. Dale Shaw, J.P., stated at the twenty-first annual meeting of this Company, held at Bradford, on Monday, that the Company

Digitized by Google

was in an eminently satisfactory position, and was able to announce the payment of 7½ per cent. on its capital, and to add £1,200 to the reserve fund, and carry forward the sum of £277. 15s. to the next account. He had the pleasing duty to announce that, owing to the regularity and efficiency of their inspections, they were still able to record that no explosion had taken place with any boiler under the Company's care since its formation twenty-one years ago. The report and accounts were unanimously adopted.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 821. Vol. XXXII. FRIDAY, FEBRUARY 9, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The Paper by Mr. W. Worby Beaumont on "The Automatic Balance of Reciprocating Machinery and Prevention of Vibration," read before the Society of Arts on Wednesday last, was remarkable in several respects. He dealt with a number of dynamical problems, and succeeded in explaining them to the audience without a single word of mathematics. By the use of plain and homely language he avoided even such expressions as moment of inertia and kinetic energy. The lecture was clearly illustrated by working models, which must be seen to be appreciated. Up to the present Mr. Beaumont has concerned himself chiefly with such reciprocating machinery as jigs and sieves, and has apparently found a complete cure for the jarring and racking of the framework, rendering, indeed, all framework unnecessary. The problem of chief interest to electrical engineers, namely, the prevention of vibration of high-speed engines, was only briefly touched upon; but it is clear that Mr. Beaumont's principle, when properly applied, will go far towards the cure of this nuisance. The practice of attempting to balance armatures by rolling them on knife edges was mentioned, and the erroneous nature of the method was explained. The following lines sum up the whole principle; but the literary style is not to be taken as a sample of the Paper which they conclude:—

> In a general way it may be said that when a piece of mechanism wants to wobble, it is obviously either wrongly constructed, or if it is not and wants to wobble, then let it wobble; but make it wobble something you want wobbled. In most cases it will not wobble so much and never so forcibly if we don't try to stop its wobbling.

Whether or no electricity will in course of time supersede all other modes of tramway traction we do not care to prophesy, but it may be predicted with some confidence that it is destined to take a very much larger share of the business than is at present the case. It is with this contingency in view that we give elsewhere in the present issue a few figures relating to tramway matters. For a country admittedly unfavourable to tramway enterprise, the totals are by no means small. Over £14,000,000 has been sunk in tramway buildings, lines, and equipment, and during the twelvemonth ending June 30, 1893, nearly 600,000,000 passengers travelled on the 960 miles of line then open for traffic. But, big totals notwithstanding, the tramway business in this country is not a mine of wealth, at least to the shareholder; the net return on this fourteen millions sterling is but a beggarly 5½ per cent., no allowance being made for depreciation, &c. Of course, some tramways are remarkably prosperous. Thus, at Glasgow, the net receipts are 9·8 per cent. on the total capital expenditure, and at Edinburgh 7·4 per cent., but on the other hand many a line works at a loss. From the figures published by the Board of Trade it would appear that where a municipality is concerned a mile of tramway is constructed on the average for a little over £11,000, as against £16,000 for a company. This on the face of it looks like a corroboration of the theory of the economy of municipal enterprise. But it would be instructive if we could discover how much of this excess is due to the bleeding of private tramway enterprise, not by the company promoter, but by the local authorities themselves. The future of electric traction in this country, like that of electric lighting, would seem to depend on its gaining the favour of the municipal mind.

Leeds has been worrying itself over this question of tramway municipalisation—firstly, as to the sum it should pay for the tramway system; secondly, as to whether it shall work the tramway system which it has purchased, or lease it out to some company. Ratepayers' opinions are divided on the second head; the first has been settled, and a purchase sum of £130,000 handed over to the vendor Company. Very curious indeed are some of the reasons in favour of municipalisation which are advanced by the ratepayers who advocate this system of working. One reason is that "a company would think first of its dividends"; another is that the city ought to know a good thing when it sees it, and "should make the greatest possible money returns" on its purchase. A third reason put forward to induce the Leeds Corporation to "have a shot" at tramway running is, that if it should fail it really does not matter, for at any time it gets tired of the game "it will be as free as it is at present to hand the undertaking over to a public company on conditions framed after actual experience of working." Is this the innocence of sweet simplicity, or is it that species of shrewdness which always has an eye on the bogus company promoter?

The use of an electric arc as a tool is to some extent restricted by the Benardos patents, and there are other practical objections to its employment either for welding or for soldering when the current is derived from the mains of a supply company, and when the work is in electrical connection with the earth. A plumber, for example, using an arc

Digitized by Google

for work on water service pipes would rather annoy the engineer of the supply station by putting twenty or thirty amperes to earth. So amenable, however, is electrical energy to transformation that the difficulty is not insurmountable. A handy form of electro-chemical blowpipe, the invention of Mr. H. N. Warren, is described in a recent number of the *Chemical News*. It consists of a simple water voltameter, arranged so that the electrolytic gases pass up a couple of tubes to the oxy-hydrogen blowpipe. Placed on the house electric light wires, say fifty in series, this apparatus ought to maintain a long, steady flame of intense temperature. Some difficulty might be experienced with the acid vessicles which are invariably carried away from the acidulated water by the escaping gases, especially where the evolution of gas is abundant. It would be very objectionable to find that acid was being carried on to the work which was being heated. To obviate this defect the gases might be passed through a pair of wash-bottles or through scrubbers.

One of the knottiest problems connected with the interior economy of Government departments is the maintenance of a healthy flow of promotion. Provided the public purse be long enough there need not be a single gray-beard in the service of the State, nor, on the other hand, provided it be compatible with efficiency, need any one be retired under three score years and ten. But as is ever the case, it is the *juste milieu* that is so difficult of attainment. An instance of this is the hubbub that has arisen in India in connection with the supposed desire of the present Director-General of Telegraphs to extend his tenure of that office until March, 1897, that is to say, two years beyond the regulation period of five years. Mr. Brooke, whose services to the State were, as was recently recorded in these columns, recognised by a New Year's Honour, will, when his term of office expires in March next year, have completed 38 years' service, all of which, with the exception of about a couple of years, have been spent in India. Notwithstanding this long record, the Director-General will only be 53 years of age on his retirement, having joined the service in the year of the Mutiny at the early age of fifteen and a-half. Length of service, coupled with comparative youth, are an unusual combination, and might well at a critical moment warrant the over-riding of a cast-iron regulation; but in the piping days of peace the arbitrary suspension of rules of this kind naturally begets a sense of injustice amongst those who do not benefit by the arbitrary act. Promotion deferred maketh the heart sick, and not least so in the Far East, where so much depends upon it. Surely the "infinite variety" of our orders of chivalry cannot be put to a more graceful use than in rewarding a servant of the State without injury to others.

The Guilds' Central Technical Institute.—The headquarters of the City and Guilds of London Technical Institute in Exhibition-road, South Kensington, is henceforth to be known as the Guilds' Central Technical Institute.

A Proposed Long Telephone Trunk Line.—According to the Vienna *New Free Press*, a scheme is on foot for connecting Vienna and Odessa by telephone. These two towns are some 700 miles apart as the crow flies.

The Heilmann Electric Locomotive.—Public trials of this locomotive will take place between Havre and Beuzeville to-day and to-morrow, two journeys being made each way each day. The distance from Havre to Beuzeville is about 15½ miles.

The Harness Case.—The week allowed by Mr. Hannay for the prosecution in the Harness case to consider whether they would proceed under the Vexatious Indictments Act having elapsed, and they having taken no steps in the matter, the case may now be considered at an end.

The Testimonial to Prof. Garnett.—In connection with this movement a preliminary meeting of subscribers was held on Saturday, January 20th. It was agreed that as it is now known that Prof. Garnett will continue Principal of the Durham College of Science until June, the subscription list should remain open until April 21st.

Appointment Vacant.—The authorities of the Bradford Technical College require a master for mathematics, physics and engineering, at a salary of £200 per annum. Applications (which must be accompanied by no more than three recent testimonials) giving age and general qualifications must be addressed to Mr. John Nutter, the secretary, by February 14th.

Telephone Trunk-Wire Extensions in Italy.—The Italian Minister of Posts and Telegraphs has under consideration a scheme, says *Industries and Iron*, for an important extension of the telephone system of the country. It is proposed to establish trunk lines between Turin, Milan, and Genoa; between Florence, Pisa, and Leghorn; and between Rome and Naples.

Memorial to the late Sir Arthur Blackwood.—The Post Office servants resolved some few months ago to raise a fund for the purchase and maintenance of a lifeboat to be named "Sir Arthur Blackwood," as a memorial of the late Permanent Secretary to the Post Office. The sum of £1,115 has been raised, and the boat when purchased will be stationed at Greenore, County Dundalk.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	October 15th, 1893
Bissao-Bolama	November 24th „
Cayenne-Vizeu	November 25th „
Garachico-Santa Cruz de Palma	December 27th „
Constantinople-Odessa	January 31st, 1894
Saigon-Thuan-An	February 1st „
St. Thome-Loanda	February 5th „

Personal.—We are informed that Mr. Gisbert Kapp has accepted an appointment with the "Verband Deutscher Electrotechnicker" in Berlin. Mr. Kapp has done such good work in this country for the last twelve years as an English engineer that his departure is a matter for regret.——Mr. J. Stewert has been appointed engineer and manager of the electric light works in Derby, with Mr. A. E. P. Moore as assistant engineer.

Expiring Patents.—The United States Commissioner of Patents has initiated an innovation that will be of value to inventors and the public generally. The *Patent Office Gazette* now gives a list of patents expiring each week. The date of issue of each expiring patent is also given. Electrical people in America will by this means know from week to week the state of the electrical business, as regards the patents covering electrical inventions.

Switching-in Motor Cars.—In case of a sudden stoppage of the current, electric tramway conductors in America are ordered to close the switches of their electric light circuit and to wait until the lamps light up before switching on the car motor, To prevent the whole load coming at once on to the engines. one set of conductors are ordered to switch the car motor on immediately, whilst another set are told to wait half a-minute, and another a minute, and so on.

Cavendish Laboratory Extension Scheme.—A syndicate, consisting of the Vice-Chancellor, the Master of Peterhouse, the Master of Christ's, Prof. Thomson, F.R.S., Prof. Liveing, F.R.S., Mr. Glazebrook, F.R.S., and Mr. Shaw, F.R.S., is about to be appointed to consider the best means of extending the Cavendish Laboratory. A site for the extension is reserved; but the standing difficulty of funds is likely to prove a serious one unless outside help can be obtained.

Digitized by Google

The Electric Lighting of Windsor.—It is said that it has been found necessary to stop running the electric light in this town. The mains laid down for the Electric Light Company are now practically useless on account of being eaten through in several places by electrolytic action. No more light will be supplied until the new mains are laid, which will be done at once if the Corporation will allow the Company to proceed

Blackpool.—At Tuesday's meeting of the Town Council it was resolved to borrow £24,000 for electric lighting extensions, over and above the £26,000 already spent. At a meeting of the Electric Lighting and Tramways Committee, on the 2nd inst., it was resolved that the terms of Mr. Holroyd Smith, for estimates of cost and supervision of the works required for placing the permanent way and plant of the tramways in thorough repair and working order, be accepted.

Air-Core Transformers.—Messrs. Bedell and Crehore inform us that Mr. Rimington's Paper on "The Behaviour of an Air-Core Transformer when the Frequency is below a Certain Critical Value," read before the Physical Society in October last (see *The Electrician*, November 3rd, p. 18), in which attention was called to the case in which the primary current of a transformer falls off when the secondary is closed, was anticipated by them in the *Electrical World*, June 17, 1893, in Article V., on the "Theory of the Transformer."

"Dielectrine."—At a recent meeting of the Société Française de Physique, M. Hurmuzescu exhibited various electro-static experimental apparatus, in which a dielectric substance called *dielectrine* was employed. According to M. Hurmuzescu, *dielectrine*, which is a mixture of paraffin and sulphur, is harder and less easily melted than the former, and less easily cracked and less hygroscopic than the latter. M. Chabaud, the electrical instrument maker, of Paris, has succeeded in turning out the material in a hard, easily-worked, homogeneous state.

Newport—The *South Wales Daily Star* states that the Electric Lighting Sub-Committee of the Parliamentary and Improvement Committee of the Corporation have, after a protracted discussion, decided to stand by the original recommendation to the Council, *i.e.*, to accept Messrs. Fowler's tender. A letter, it is further s ated, was received from Messrs. Crompton offering to carry out the whole of the contract at a sum even less than their previous tender, and further undertaking to run the whole installation by contract over a series of years, upon terms which would leave the Corporation an absolute profit on the transaction from the very first.

Operating Lock Gates Electrically.—Mr. Thomas Monro, Superintendent of the Soulanges Canal in the Province of Quebec, has experimented with an electric motor, which transmits power through a train of gears to a pinion which works into a rack placed on the side of a 6in. I beam. The end of this beam is attached to the top of a lock gate which it shuts or pulls open as may be required. The operation takes about 55 seconds, and is performed with perfect ease. It is proposed to operate two pairs of gates and four filling and emptying sluices from one point in the centre of the lock, and upon whichever side may appear advisable.

Electric Light and Coast Defence.—In a lecture on "Some Aspects of Coast Defence," recently given at the Royal United Service Institution, Col. J. B. J. Jocelyn, R.A., argued that the question of electric light was in an unsatisfactory state. The creation of a large and brilliantly illuminated area might work well if a very large number of pieces bore upon a narrow obligatory place of passage, but it seemed to him impossible to make certain of stopping, at night, a swarm of torpedo-boats by defences at one portion only of a channel. The arrangements for electric lighting should not be left to be settled under the pressure of imminent war, and the present uncertainty was a serious embarrassment to the preparation of practical schemes of defence.

Gas and Electric Lighting Concessions in France.—As we have frequently recorded disputes are constantly arising between gas companies and municipalities in France on account of the violation by the latter of contracts entitling the companies to a monopoly. St. Etienne and Montluçon were three years ago ordered by the Conseil d'État to compensate the gas companies for allowing the introduction of the electric light. Recently the same tribunal gave judgment in favour of a claim for the assessment of damages by the gas company of Argentan against the municipality. The latter had not only allowed an electric light company to lay down wires, but had allowed it the use of a site for its works. The judgment contains a recital that, whenever a gas company has been accorded a monopoly for any fixed period, compensating advantages have always been given to the local authorities in the shape of cheap rates or participation in profits.

The Accident at Prescot.—An inquest was held at Prescot on Thursday last week on the body of Henry Waide, 14, employed by the British Insulated Wire Company, which light Prescot by electricity. On the previous day the boy was engaged with an electrician named Jones in a cellar of some premises in Eccleston-street. Jones left him for a few minutes, and on his return found him lying on the floor. The lad's finger and thumb were burnt, showing that he must have pulled the wire. Jones said that Waide was a careful lad and knew the danger. The wire was insulated, and was put up two days before. The joint was broken by some means where he touched. The pressure was 2,000 volts. They were about to fix a wooden guard over the transformers. The wire had evidently been grasped, as it was pulled from its position. The boy had no right to touch the wire. He had been at the work for five months. The jury found that the boy died from electric shock.

The Science and Art Department.—The following permanent inspectors have been appointed under the Science and Art Department :—E. J. Ball, Ph.D , Instructor in Assaying, Royal College of Science, London; R. Blair, M.A. (Edin.), B.Sc. (Lond.), Head Master of the Public School of Science, Cheltenham ; S. F. Dufton, M.A., D.Sc., Fellow of Trinity College, Cambridge; C. Geldard, M.A., formerly Scholar of Trinity College, Cambridge; H. H. Hoffert, D.Sc., Demonstrator in Physics, Royal College of Science, London ; Prof. D E. Jones, B.Sc., late Professor of Physics, University College of Wales, Aberystwyth, Director of Technical Education under the Staffordshire County Council; D. S. McNair, B.Sc. (Lond.), Ph.D., Lecturer in Chemistry at the People's Palace, Mile End, London ; C. McRae, M.A., late Scholar of Exeter College, Oxford, Assistant-Examiner and Occasional Inspector for Science, Department of Science and Art; T. Preston, M.A., Fellow of Trinity College, Dublin, and Professor of Physics to the Catholic University, Dublin ; F. Pullinger, M.A , B.Sc., late Burdett Coutts' Geological Scholar, Oxford, Organising Secretary of the Technical Instruction Committee of the Devonshire County Council; Gapt. T. B. Shaw, R.E., Occasional Inspector of the Science and Art Department ; H. Wager, Lecturer in Botany at the Yorkshire College, Leeds. It is proposed that these gentlemen should each take charge of a special district, and reside in one of the chief towns in their district.

The Eckert Bimetallic Wire Patent.—A patent has been recently issued to Mr. W. H. Eckert, 80, Broadway, New York, for an improvement in telephonic transmission, and, generally, in the distribution or transmission of rapidly alternating currents, the claims of which, says the *Electrical World*, are startling in their character. Mr. Eckert, says our New York contemporary, "is so well and honourably known in the electrical circles, however, where he has occupied positions of the greatest prominence, that claims made by him are entitled to respectful consideration, particularly as they relate to a branch of electricity in regard to which, with our present knowledge, it would be hazardous to dispute the improbability of any assertion from a competent source." According to the patent specification the invention for the most part consists in the discovery that telephonic transmission, or rapidly alternating currents in general, may be more perfectly effected upon a bimetallic conductor, such as steel and copper in substantially equal parts, than upon a conductor of one material, such as copper ; and with the advantage that such transmission may be effected upon a circuit consisting of a single composite wire and an earth return as perfectly as though two copper wires, each of equal conductivity, were arranged in a closed metallic circuit. It has also been discovered that less insulation is

Digitized by Google

needed to protect a bimetallic wire than is necessary for copper or other single-substance conductors, in the transmission of rapidly alternating currents. The patentee has no theory to account for his claims.

Obituary.—We regret to announce the death of Mr. G. B. Prescott, at New York, at the age of 63. He was born in Kingston, N.H., September 16, 1830. After leaving school, in 1850, he engaged in the telegraphic business as an operator, and was employed in 1850 and 1851 in the Boston office of the Merchants' Line, which was then working the Bain chemical system between that city and New York. Soon afterwards he entered the service of the Commercial or "House" line in the same city, where his marked ability as an operator and electrician soon raised him to the position of superintendent of that line, and also of the local system known as the "Marine Lines," extending from Boston to Cape Cod and Cape Ann. In 1859 a general consolidation of the competing telegraph lines in New England occurred, after which Mr. Prescott was appointed to the superintendency of a district comprising most of the lines in western New England, with headquarters at Springfield. In the course of the controversy respecting the proposed establishment of a Government telegraph, which raged with much vehemence in 1868-69, Mr. Prescott took a prominent part in opposition to the scheme. One of his statistical articles, published in a local newspaper, presented his views of the matter in such a forcible way that the attention of President William Orton was attracted by it, which led to the removal of the author to New York, and to his employment in the general office of the Western Union Company in more extended services of the same character. When the office of electrician of the company was established, Mr. Prescott was chosen to fill the position. Mr. Prescott was the author of a number of works on telegraphy and allied subjects, among which are his "History, Theory, and Practice of the Electric Telegraph," 1860; "Electricity and the Electric Telegraph," 1876; "Speaking Telephone and Talking Phonograph," 1878; and "Dynamo Electric Machines."

A Curious Electrical Fire.—One of those peculiar complications which sometimes arise in connection with losses chargeable to electricity was adjusted by the Supreme Court of Massachusetts a few weeks ago. The building and machinery of an electric company had been insured against fire. The fire itself was confined to a remote corner of the building, but it established a short circuit between two of the lightning-arresters, which short-circuited a dynamo. This increased the strain on the gearing, which, in its turn, broke a jack-pulley. The jack-pulley destroyed the governor. The loss of the governor wrecked the fly-wheel, and the whole machinery went to pieces. In the opinion of the Court fire was the direct cause of loss. It was, remarks the *Insurance Monitor* of New York, "a curious and complicated chain of causes, and while other Courts would probably have held the same view, the connection between the fire and the ultimate destruction of the machinery seems a very remote one. The incident suggests numerous variations which might have made a still more complex question. For instance, the machinery might have been in a separate building. That building might have been covered either as a separate item in the same policy or under an independent contract, or the building containing the machinery might have been any distance away, and insured in another company altogether. Mere distance was not an essential element in the reasoning. The continuity of the casualty was not affected by the length of wire through which the current had to run. The causes would have operated after the same fashion if the fire had occurred in New York and the dynamo and its engine had been planted at Niagara Falls. But it would require a great stretch of imagination to talk of a fire damage at the latter which was an integral part of a small fire occurring in the former. Such illustrations show the haziness of the logic by which this chain of causes was defined as so many subordinate features of the original fire."

The Gibbs Light and Heat Tender. — The Chicago, Milwaukee, and St. Paul Railway Company, says *Engineering*, began experiments in 1889 to devise an economical and reliable system of electric train lighting. The first plan tried was the combined accumulator and direct-current system. The service in which the lighting was used related to heavy through express trains, making a continuous run of 430 miles daily. As these trains were practically a unit for the entire distance, it was considered feasible to use a direct-current lighting system, doing away entirely with batteries. By using in such a system a moderately high-speed engine, belted to a reliable type of dynamo, there seemed to be no reason why the lighting should not be as unfailing as in the case of stationary isolated plant. Upon this basis the present system was introduced, and has been in very successful use up to this time. The cars equipped to date for electric lighting, upon the St. Paul Railway, are about 100 in number, and six through trains are run each night so lighted. These trains are from seven to ten cars in length, and the number of lamps lighted varies from 150 to 225 per train, the lamps being 110-volt, 16 candle-power incandescents. After the introduction of the system, some difficulty was experienced in obtaining in winter, when the weather is often very severe—the thermometer at times falling to 35 degrees Fahr. below zero—sufficient steam of regular pressure from the locomotive to give uniform light. At such seasons the problem is further complicated by the use of steam from the locomotive for heating the train. Experiment proved that in zero weather about 1 per cent. of the steaming power of the locomotive was required to heat each car. It therefore became an open question whether it would not be more economical and practicable to use a separate boiler for heating and lighting. Accordingly the "light and heat tender," was designed, and two were built. The use of these cars has been an entire success, and up to the present they have run about 196,000 miles each without a single mishap. The reason for their success may be found in the fact that, while they add to the resistance of the train, the additional steam required for hauling them passes through the cylinders and the blast-pipe, and so urges the fire, while without them the drain of steam for heating and lighting is a dead loss, adding nothing to the capacity of the furnace to burn more fuel. The car is a complete central heat and light station on wheels. It is run immediately behind the locomotive tender, is 34ft. long, very strongly built, and encased in sheet steel. Including full equipment of boiler, engine, dynamo, storage for three tons of coal and 270 gallons of water, it weighs 64,000lb. It is carried upon two four-wheeled trucks of the usual American pattern. The interior is divided into two sections: a boiler-room with coal tank, and an engine-room with the water tank set on edge at one side. The boiler is of the locomotive pattern, the crown sheet being supported by radial stays, and the firebox and ash-pan inclosed in a water bottom. The feed water is normally obtained by means of the injector pump, pulling the water over from the locmotive tender through a rubber hose; in case of failure of this supply, however, the water in the car tank is used, and is calculated to be about two hours' supply. The engine is a Westinghouse automatic, with cylinders 6½in. in diameter by 6in. stroke, capable of indicating 18 horse-power with 100lb. steam. This engine is belted to a 15-kilo-watt Edison dynamo. The exhaust from the engine may be run either directly to the air through the "exhaust head" in the roof, or may be sent through the boiler uptake to urge the fire. One special attendant is run with this car, and he is expected to perform all the operations of firing the boiler and regulating the light and heat for the entire train. The great feature of the car is its ability to supply at all times ample steam for heating and for a reliable light, without expensive batteries or complicated machinery. The value of this feature is most appreciated in bad weather; at such times the drain upon a locomotive is greatest for hauling the train, so that it is at least able to stand an additional drain for lighting and heating, and at the time when the requirements for these are most urgently needed. The boiler in the car has been found sufficient to heat ten cars in the severest weather, and to supply power for 250 lights. In summer, when steam is not required for heating, the tender cars are laid off and the lighting outfit placed in the forward end of the baggage car, steam for the engine being taken from the locomotive. The apparatus is the same as that above described, and the manner of handling is the same.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 345.*)

Flame.—It will be well, at this stage, to consider more fully some of the phenomena attending the combustion of coal and other fuels. One of the most important of these to the engineer is the production of flame. There are two kinds of flame: the one arises from the combustion of volatilised portions of the fuel; the other arises from the combustion of the inflammable gases produced by the imperfect combustion of the fixed, or non-volatile, portions of the fuel. The first kind of flame is luminous, and possesses a bright yellow or reddish-yellow colour; and it is usually long and abundant. It arises from the fact that a considerable part of the fuel is volatilised by the furnace heat before it can receive oxygen enough to burn it. The inflammable gases thus formed pass upward and burn, at some height above the solid fuel, in the shape of flame. These flames are composed of various hydrocarbons, produced by the destructive distillation of the bitumen or resins in the solid fuel; and they owe their luminosity to the presence of minute particles of solid carbon in great abundance. The carbon particles are developed by the precipitation of elementary carbon, and the formation of higher hydrocarbons, when the lower or heavier hydrocarbons become raised in temperature very much above their vaporising point. Such flames are a necessary contingent upon the use of fuels with volatile components; and, properly treated, are a source of economy in the furnace. The second kind of flame chiefly arises from the production of carbon monoxide, and the subsequent combustion of this gas. The air supplied to the fixed carbon will, if not abundant, produce combustion in one stage only, forming the lower carbon oxide. When this gas has ascended above the level of the fuel it meets with fresh oxygen and burns with a faint, short blue flame. Very dry coals and coke usually burn with short flames and well-concentrated heat, or "glow-fire"; but it is sometimes convenient and efficient to cause the flame to become longer by deferring the combustion of the fuel. In order to do this the solid must be turned into gaseous fuel in greater proportion than occurs in the dry fuel. This is effected by moistening the solid fuel with steam or water; either directing a steam jet on to the fuel or previously damping it, or placing water below the grate so that it is evaporated and passes up with the air through the solid fuel. The following chemical reaction takes place:—

$$H_2O + C = H_2 + CO.$$

The C is supplied by the solid fuel, while the two gases, H and CO, which are produced, give rise to lengthy flames. Moisture occurring in the composition of a fuel will, of course, give rise to deferred flame-combustion in a similar manner.

Smoke.—Another highly-important circumstance attending combustion of fuel is the production of smoke. Smoke consists of a mixture of finely-divided particles of carbon and heavy, oily hydrocarbon with the products of combustion. Ammoniacal compounds also add to the smoke, and give it a thick whitish appearance. Smoke is therefore indicative of imperfect combustion; and for this, as well as for other reasons it is to be avoided. The direct cause of smoke is the incomplete combustion of volatile hydrocarbons; and the conditions which produce it are as follows. To produce smoke there must be the combustion of bituminous or resinous or other volatile hydrocarbon fuel, together with one of the conditions following:—(1) an insufficient supply of air, (2) too great an excess of cold air, (3) improper distribution of the supply of air, or (4) premature abstraction of the heat of the flame, sufficient to reduce its temperature below the combustion point. With an insufficient supply of air, while the volatile matter is turned into gas by the furnace heat the air is robbed of its oxygen by the fixed carbon, so that there is not sufficient oxygen in the space above the solid fuel to burn the combustible gases. These gases pass into a colder part of the furnace, forming smoke. With an excess of cold air, over and above the proper excess, smoke arises from the fact that the large bulk of cold air admitted into the region of the flame is sufficient to cool the flame below that temperature at which it is capable of combustion. The result is that excess of air and unburned smoky fuel pass away together. An improper distribution of the air supply may cause smoke from the fact that the combustible hydrocarbons are not properly mixed with the air, or from the fact that the mixture takes place too late in a part of the furnace which is not sufficiently hot. Premature abstraction of the heat of flame may arise from the contact of the flame with relatively colder surfaces of metal, on the other side of which there may be water. If this abstraction is so great as to lower the flame-temperature below the combustion point, while yet there is unburned hydrocarbon gas in the flame, smoke will inevitably result. From the conditions of its production it is evident that smoke is more liable to be produced when first the fuel is thrown into the furnace than after the greater portion of the volatile matter has been evaporated out. And the density of the smoke will, other things being equal, be greater in proportion to the richness of the fuel in hydrocarbons, as well as to the suddenness with which it is heated. The tendency of a fuel to cause smoke is usually measured in terms of the shade and the number of minutes during which smoke can be seen issuing from the chimney after a charge has been distributed over the furnace grate. This is a crude method of measurement, but is a fairly practical one. Some engineers and steam-using associations employ a graduated coloured scale of shades, with gradations from white to dense brown and black, each shade having an index number. There is no uniform adoption of such a scale, nor any generally recognised system of measuring smoke density. It is evident that by suitably regulating the quantity and the distribution of the air supply, as well as by enabling richer fuels to gain the furnace temperature more slowly than poorer ones, it will be possible to prevent smoke and to obtain almost, if not quite, perfect combustion. Turning now to fuels which are not bituminous, and which, therefore, cannot develop smoke, we must notice that these are none the less liable to become imperfectly burned. In the one case the incomplete combustion is visible; in the other case, though equally real, it is insidiously invisible. Any of the causes which develop smoke in the case of bituminous fuel, may lead to the escape of unburned carbon monoxide where fixed carbon only is concerned; and the perfect invisibility of this gas renders the faulty condition less easy of detection. In every case the direct remedy lies in the proper regulation of the supply of air to the fuel.

Coke.—The combustible portion of coke is almost entirely fixed carbon, the remainder of its weight being made up of a small amount of mineral matter and the water which the coke has absorbed. In coking a coal the mineral matter is of course left behind in the coke, so that the percentage of ash can be calculated from an analysis of the coal. The percentage of water, which is all hygroscopic, can be obtained from the loss of weight of a sample of coke after several hours' desiccation at a high temperature in a current of hot air. The remainder, after these two have been subtracted, will generally be found to be pure carbon, and the thermal value of the fuel, as well as the air concerned in its combustion, can be calculated from this remaining percentage. Sheltered coke will gradually absorb water amounting to from 15 to 20 per cent. of its weight when taken from the retorts, the amount of water depending upon the porosity of the coke. Exposed to rain, it will retain as much as 50 per cent. of its weight of water. The porous character of coke is determined by the nature of the mother coal, highly bituminous coal giving, in general, a very porous residue of coke. This property in coke is valuable on account of the facility to the access of air which it gives in the combustion of the fuel. According to analyses by Dr. Muspratt, the average of 19 samples of coke from British coals gave 93·44 per cent. of carbon, the samples having been previously desiccated. About 10lb. of air will be chemically required for the complete combustion of this average sample, neglecting air required for dilution, and the total heat of its combustion would be equal to 13,550 units per lb. of the fuel. This would give an evapora-

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

tive power of 14lb. of water, from and at 212° Fah. The heat produced by the combustion of coke is very regular, the character of the heat remaining constant during the entire process; and it may be made very intense by the aid of a rapid supply of air. On the other hand, the heat is almost entirely concentrated within a space quite close to the solid fuel itself, there being practically no luminous flame and only a short non-luminous flame of carbon monoxide. Coke, is, of course, perfectly free-burning and smokeless.

Wood and Straw.—When coal and its products are unobtainable or excessively dear, it is a common practice to use dried wood-tissue, either of trees, corn stalks, or in some countries sugar canes, as fuel. Intrinsically, all these things are inferior combustibles, owing to the large amount of water contained in them; but, from a commercial point of view, they are often superior to coal and enable a motive-power plant to be carried on more cheaply that if this richer material were purchased and used. Wood-tissue from trees does not appear to differ very much in composition among the principal exogenous trees nor among the various parts of any one tree. When cut down and air-dried for a considerable time such fuel still retains as much as 25 per cent. of its weight of water, besides a considerable proportion of lower hydrocarbons containing oxygen. There is therefore very little active fuel stuff in the tissue; and what there is has to evaporate a large burden of water in the fuel itself. There is consequently very little heat available for external and useful heating. The following analysis represents an average sample of air-dried timber:—

Water (hygroscopic)	25 per cent.
Carbon	37·5 ,,
Hydrogen	4·5 ,,
Oxygen (other than in water)	30·75 ,,
Nitrogen	0·75 ,,
Ash	1·5 ,,
	100·00 ,,

This sample of fuel has an evaporative power of only six pounds of water, from and at 212° Fah., per pound of the fuel, the weight of water evaporated including the quarter of a pound of water in the fuel itself. Its external evaporative power is therefore only 5·75lb. Wherever possible the thermal value of wood should be improved by drying it at a high temperature, waste heat of some sort being utilised for this purpose. After being raised to 284° Fah. for some time, the foregoing quality of wood has been found by M. Chevandier to have the following improved composition:—

Carbon	50 per cent.
Hydrogen	6 ,,
Oxygen	41 ,,
Nitrogen	1 ,,
Ash	2 ,,
	100 ,,

Even this, however, is a poor fuel, possessing an evaporative power of but little over 8lb. The thermal value of wheat straw is about 7lb. of water evaporated from and at 212° Fah.

Fuel Testing.—Estimating the thermal value of a fuel upon the basis of its chemical analysis, although giving results which are of some importance and which indicate the theoretical merits of the fuel, is manifestly not sufficiently practical to be considered as final by an engineer. Reasons have already been stated why it is not possible to trust the mere chemical analysis of a fuel, in determining the available heat of its combustion; and what is needed, in addition to the chemical estimate, is an experimental method of actually measuring the total heat of combustion of a sample of fuel, as a check upon the chemical estimate. Two coals from different seams, for example, which may be found to have exactly the same chemical analysis, as regards the percentages of the elementary constituents, will yet be found very frequently to have quite different thermal values when actually tested in a calorimeter. But beyond even this, there is the important fact that neither the actual nor the estimated heat of combustion is necessarily a prime index of the value of a fuel, as compared with any other fuel, when the two are used in furnaces under ordinary conditions. The better fuel, as regards its total heat of combustion, may and often will be found to give results in practice which are inferior to those given by a chemically poorer combustible. Again, two fuels which may have the same thermal value, as estimated or experimentally determined, and which may give equally good results in the same furnace, when the furnace is kept at full load and under normal conditions, will frequently be found to possess very different values when the conditions of their combustion are made slightly abnormal, either by a fall or an excessive rise in the load on the furnace, or by some variation of draught or quantity of fuel in the furnace. There are, therefore, three kinds of fuel tests which are of importance to the engineer:—(1) calorimeter tests, by which the total heat of combustion is actually measured; (2) short furnace trials under normal conditions, by which the normal commercial value of the fuel, in regard to the actual type of furnace employed, is determined; and (3) long furnace trials under all the varying conditions of actual practice, by which alone the suitability of any fuel to the particular class of work it will have to do can be satisfactorily determined. We will now consider more fully the first of these, leaving the others for consideration after we have studied the various types of practical furnaces.

Calorimeter Tests of Fuels.—Select eight or ten small pieces of the fuel having an average appearance, and reduce them to a fine powder in a clean and dry mortar, taking care to thoroughly mix the samples. Sift off the larger powder and reduce this to finer powder, repeating the operation till the whole will pass through a fine sieve. Then weigh out about two grammes of the powder in a chemical balance, noting the weight to at least four figures, and set the weighed sample aside in a dry place. Next, prepare the oxygen mixture which will be used for the combustion of the sample. This mixture is usually kept ready made up, but requires to be dried and reduced to the finest powder immediately before use. The oxygen mixture may be made up of one part of saltpetre to three parts of chlorate of potash; though sometimes only the latter chemical is used. The salts must be of the purest quality and especially free from any organic impurities, such as dust. Water, either of crystallisation or hygroscopic, must be removed from the oxygen mixture immediately before the test by drying the salts at a temperature of from 220° to 300° Fah. in an air bath. When quite cold the dried mixture should be reduced to a fine powder in a clean and dry mortar, and by no means in the mortar which was used for the fuel unless every trace of the fuel stains has been removed. The function of the mixture is to supply oxygen to the fuel, and it will be necessary to provide sufficient of the salts to ensure complete combustion of the entire weighed sample. It will be best to calculate the weight of mixture which will theoretically be necessary, and then to allow a very wide margin by supplying excess of the salts. Usually from ten to fifteen times the weight of the fuel sample is taken, according to the amount of volatile matter in the fuel. Having weighed out the oxygen mixture, the two powders must next be intimately mixed, care being taken to use the whole of both weighed powders. The whole is then placed in a suitable small furnace inside a water calorimeter and ignited. Vigorous chemical action ensues, and the heat of combustion is passed through the metal walls of the furnace into the water. The weight of water in the calorimeter is known, having been previously measured, and the rise of temperature of the water is ascertained by means of a thermometer. The number of British units of heat added to the water can be calculated from these two data. Besides the heat given to the water, a portion of the heat of combustion is retained by the furnace and its contents. The proportion between the two can be ascertained by experiment with a fuel of known thermal value; and the constant for each particular form of fuel-testing calorimeter is usually supplied with the instrument. If the heat added to the water is multiplied by this constant, the product will give the total thermal value of the sample of fuel. Various forms of calorimeters are used

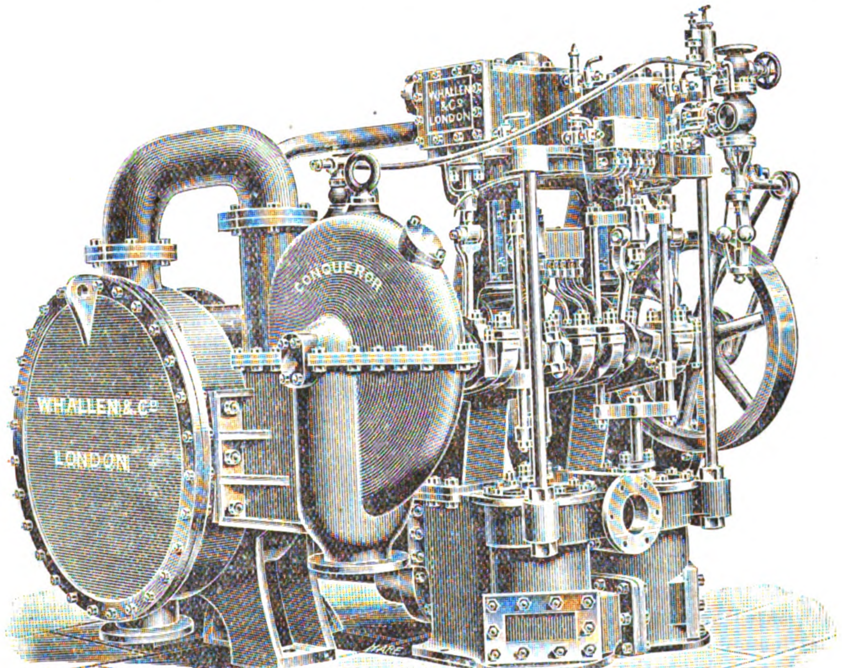
Digitized by Google

for this purpose. In some the sample of fuel is contained within a cylindrical copper furnace placed beneath a bell jar in a glass vessel of water, the products of combustion bubbling up through the water from the inverted mouth of the bell jar, and giving up their heat to the water. Some are placed within thick cylinders of concrete, to prevent escape of heat by radiation. Some are ignited by a time fuse, which is lit by hand before the furnace is immersed in the calorimeter water; others are ignited by a drop of strong sulphuric acid let fall on the mixture; while in a recent form of calorimeter the ignition is effected by a spiral of platinum wire in the midst of the mixture, the spiral being rendered incandescent by a measured supply of electrical energy. It will be seen from this brief description that the calorimetric determination of solid fuel is by no means a difficult, complicated, or expensive process; but that it is one which any works manager or generating-station engineer could very well, after a little practice, conduct for himself. The check on the quality of fuel supplied would be much more complete if this were more frequently and extensively done by managing engineers. All the apparatus that is necessary can, with the exception of a delicate chemical balance and a set of gramme weights, be obtained in sets for the purpose, costing little and requiring no more than the care ordinarily expended on electrical testing apparatus in use.

(To be continued.)

ALLEN SELF-CONTAINED CONDENSING PLANT.

We illustrate this week a novel form of combined condensing plant designed and manufactured by Messrs. W. H. Allen and Co., of York-street Works, Lambeth. The feature of the design is that all the parts are combined and form one complete machine, so that the space occupied is much less than with the most modern improvements. The condenser is circular in form, the body being of cast iron, with gunmetal tube plates and tubes, the tubes being secured by a special form of ferrule, so that they cannot become slack, and leakage is entirely prevented. The plant is particularly suitable for



in the ordinary arrangement. There are two air pumps and one centrifugal circulating pump, all worked by the same engine, the air pumps being driven from the engine crossheads, and the circulating pump direct from the crankshaft. The engine is of Messrs. Allen's compound type, and fitted moderate-size electric-light stations, and has been specially designed for this class of work. For very large lighting stations Messrs. Allen construct their condensing plants on a different plan, the condenser and machinery in such cases being separate.

THE ELECTROLYSIS OF SALTS OF THE ALKALI METALS.

BY BERTRAM BLOUNT, F.I.C.

During the slight lull in the endeavours of inventors to put the production of alkali and bleach by electrolysis upon a commercial footing, which has distinguished the last half-year from that which preceded it, an opportunity presents itself to examine rather more closely than was practicable previously the nature of the reactions upon which the electrolysis of the salts of the alkali metals primarily depends. The subject is engaging attention abroad, two Papers of interest having appeared, one by Nourrisson before the Chemical Society of Geneva, and the other, which is in some sort a commentary on the first, by Oettel, in the *Chemiker Zeitung*. The chief facts and conclusions with which they deal appear worthy of consideration, both from their electro-chemical interest and their technical significance.

The fundamental relation which exists between the chemical energy involved in the reactions taking place in an electrolyte and the voltage, either requisite to induce those reactions when they are endorthermic or conversely resulting from the occurrence of the reactions when they are exothermic, permits of the calculation of the critical voltage corresponding with a given electrolytic reaction from thermo-chemical data. Our present incomplete knowledge of these data sometimes obscures this relation, and renders results deduced therefrom inaccurate, but in many instances the links of connection are known with

Digitized by Google

a sufficient approximation to exactness to be immediately available. Thus, in the present case, the efficiency in terms of energy of such processes for the electrolytic manufacture of alkali and bleach as have reached the stage of large-scale experiment, can be determined closely enough for all technical purposes.

Taking the case of the decomposition of sodium chloride and accepting the usual values for the heats of combination of sodium chloride and water and allowing for the formation of oxygenated compounds of chlorine, the measure of the energy required for the electrolysis of an equivalent of sodium chloride in aqueous solution is 470 Cal., corresponding with 2·02 volts. Similarly, the decomposition of sodium sulphate requires 2·15 volts. Extending his investigations in this direction, Nourisson has arrived at the conclusions that the voltage requisite for the decomposition of all the alkali salts of the same acid has the same value, and that, as the heat of neutralisation of all oxyacids is nearly identical, the critical voltage for the electrolysis of their salts is also nearly a constant quantity. The rational character of these conclusions is evident from a comparison of the observed and calculated values which are given below:—

——	Chloride.	Bromide.	Iodide.	Sulphate	Nitrate.
Potassium	2·00	1·76	1·15	2·40	2·32
Sodium	2·02	1·71	1·19	2·40*	2·36
Lithium	2·01	...	...	...	...
Calcium	1·95	1·71	1·16	...	2·28
Barium	1·94	1·72	1·17	...	2·37
Ammonium	1·83	1·46	...	2·29	...
Calculated value	2·02	1·70	1·16	2·15	2·07

On examining these figures it will be noticed that the chief tendency to irregularity is in the ammonium salts, a result quite consistent with the fact that the radicle corresponding with the alkali metal of the remaining members of the series is itself capable of reactions impossible for an elementary substance. The uniformly higher voltage needed for the electrolysis of the sulphates and nitrates than is deducible from the heat of combination of these salts, is noticeable, and indicates that the process of electrolysis takes place less smoothly than it would were it confined to the decomposition of the salts into acid and base. In the case of the sulphates the formation of persulphuric acid is a probable explanation of the discrepancy, but in that of the nitrates no corresponding change suggests itself in the present state of our knowledge. It does not follow that no such change takes place, for the potentialities of nitrogen are far from being exhausted, as witness that most remarkable substance azoimide. The settlement of these points may, however, be left for the time, inasmuch as the only alkali salt commercially electrolysed as yet is sodium chloride, the critical voltage of which is known within a small proportion of its value. When this voltage is compared with that claimed to be used by inventors of plant designed to oust the carbonating tower, the salt-cake furnace and the chlorine still at a stroke, a large divergence is apparent. Instead of 2·02 volts, or thereabouts, the best claimed is not less than 4, and 5 or more may be set down as generally nearer the mark, whence it follows that the theoretical efficiency of such a plant is not more than 50 per cent., and its actual efficiency 40 per cent. or less. A process is not necessarily unworkable with an efficiency of this order where the product has a value in the market only remotely related to its energy value, but it is just as well to realise that with the most recent figures determined by experiment, and checked by calculation from other experimental data totally independent in origin, more than half the electrical output of a plant for the manufacture of alkali and bleach is wasted by causes that cannot be considered altogether inevitable.

The Giffard Prize.—The Société des Ingénieurs Civils, which has been entrusted with the task of selecting a subject for the Giffard Prize Competition, has chosen the following:—The electric transmission of power, either to workshop tools, to railway or tramway engines, or to bridge, ship, dock and yard machinery, &c. The prize will be awarded in 1896 and will be worth £240.

TRAMWAY STATISTICS AND FINANCE.

The growth of "municipalisation," coupled with the recent decision in the Court of Queen's Bench concerning the valuation of tramway property when acquired by a Local Authority, and the possible adoption of electric traction, combine to add interest and importance to the Board of Trade statistics relating to tramways, and the following figures, based on some recently published in the *Glasgow Herald*, serve to show how the tramway has developed in the United Kingdom:—

Mileage and Financial Summary for United Kingdom.

——	No. of under-takings.	Length open for traffic.	Capital expenditure on lines and works open for traffic.	Total expenditure on capital account.
		m. ch.	£	£
‡ Tramways belonging to Local authorities	35	274 27	2,307,003*	3,105,636*
Tramways belonging to other than Local Authorities..	118	686 45	8,494,149†	10,998,516†
Total U. K.	153	960 72	10,801,152	14,104,152

* These figures include the amounts expended by lessees on buildings and equipment for working the line.

† These figures include cost of buildings and equipment in respect of the lines of Local Authorities worked in conjunction with other lines.

‡ Tramways belonging to, are not necessarily worked by, Local Authorities.

From these figures it will be seen that the average total capital expenditure per mile of line open for traffic is close on £14,700. In the case of the 274 miles of line constructed by Local Authorities this figure averages £11,335, and for the 686 miles of Companies' lines £16,032.

The distribution of total capital expenditure over the three parts of the United Kingdom up to June 30, 1893, is: England, £11,418,828; Scotland, £1,399,355; Ireland, £1,285,969. The total capital expenditure during a term of years thus appears, for the whole United Kingdom:—

Total Capital Expenditure, 1878—1893.

1878	£4,207,350	1891	£14,162,650
1882	8,261,815	1892	13,870,234
1886	12,573,041	1893	14,194,152
1890	13,786,762		

The greatest development, it will be observed, was made between 1882 and 1886. The figures relating to more recent years have been considerably affected by rearrangements of capital, the transfer of old undertakings to new companies with reduced capital, and by defective returns. Passing now from capital we invite attention to the following

Details of Rolling Stock and Passenger Traffic.

—	England and Wales.	Scotland.	Ireland.
Length of lines, miles open for traffic	761	86	113
Number of horses	23,653	4,356	2,216
Number of locomotives	522	20	21
Number of cars	3,327	429	342
Number of passengers carried in year ended June 30, 1893..	476,928,832	82,095,160	39,265,517

The development of the passenger traffic which has now attained a grand total of nearly 600,000,000 per annum, is very remarkable, and it is interesting to note how this stupendous figure has been reached. The following shows the total number of passengers carried in the United Kingdom in the same years as selected for comparisons of capital:—

Year.	Total passengers carried.	Year.	Total passengers carried.
1878	146,001,223	1891	565,621,478
1882	257,760,060	1892	581,678,546
1886	384,157,524	1893	598,289,509
1890	526,369,328		

At what cost has this enormous traffic been carried? What have the public paid for it? And what have the companies received from it? The following tables will show this at a glance:—

Digitized by Google

1853.	England and Wales.	Scotland.	Ireland.
Gross receipts	£2,904,026	£444,438	£257,640
Working expenses...	2,298,573	347,482	191,391
Net receipts	605,453	96,956	66,248

—	Gross receipts.	Working expenses.	Net receipts.
1878	£1,145,165	£868,316	£230,956
1882	1,970,350	1,556,793	414,557
1886	2,630,338	2,021,556	608,782
1890	3,214,743	2,402,800	811,943
1891	3,429,686	2,630,929	79?,757
1892	3,531,431	2,853,3?6	678,075
1893	3,606,095	2,837,446	768,649

On a total capital expenditure of £14,194,152 the net receipts for 1893 amount to a trifle over 5½ per cent., without, however, allowing for depreciation of ways, plant, motors, &c. Thus the tramway business is by no means a mine of wealth; and there are several instances in which the receipts only equal the expenditure or leave an actual loss. It is also of interest to note the remarkable difference in *net* earning power of a mile of tramway when laid in Scotland (£1,127), in England (£795), or in Ireland (£586).

At the date of the Board of Trade returns only three Local Authorities or Corporations were working their tramways under special Parliamentary authority. These Corporations were Blackpool, Huddersfield, and Plymouth.

The Blackpool Tramways have been worked by the Local Authority since September 19, 1892, and the returns cover the period between that date and June 30, 1893. The capital expended is £28,964, of which £21,976 has been laid out on lines, works, and buildings, £2,619 on engines, £1,691 on cars, £686 on Parliamentary expenses, and £1,992 on miscellaneous expenses. The total length of line open for traffic is two miles, the gauge is 4ft. 8½ins., the use of mechanical power is authorised, and the following are the working results.

Blackpool Corporation Tramways.

Gross receipts—

From passengers	£4,638	
From parcels and mails	3	
From other sources	214	
		£4,855
Working expenditure—		
Maintenance of way and works	704	
Locomotive power	456	
Repairs and renewals of engines	598	
Ditto of cars	215	
Traffic expenses	872	
Management	60	
Rent	33	
Rates and taxes	412	
Other expenses	124	
		3,474
Net receipts		£1,381
Number of passengers carried	665,112	
Number of miles run by cars	95,718	
Number of cars	10	

The Huddersfield tramways have for some years been worked by the Corporation. The length of line open for traffic is 18½ miles, of which only one mile is double line. The gauge is 4ft. 8½in. The capital expenditure has been £133,625. The use of mechanical power is authorised, and the following are the working results for the year ended June 30th last:—

Gross receipts	£24,229
Working expenses	£19,279
Net receipts	£4,950
Number of passengers carried	3,732,320
Number of miles run by cars	371,·97
Number of locomotive engines	24
Number of cars	22

The net receipts, it will be seen, are equal to about 3¾ per cent. on the expended capital, and are at the very moderate rate of £275 per mile. The fares are not stated.

The Plymouth tramways have been worked by the Corporation for only a short time, and not much instruction can be gained from the figures. It would appear that the receipts have just covered the expenditure, so far as the work has gone.

We conclude with a table giving some statistics relating to four large leading tramway concerns:—

Statistics of the Birmingham, Leeds, Edinburgh, and Glasgow Tramways.

Company.	Miles of line open.	Motive power.	Capital Expenditure.	Ditto per mile.	Gross receipts.	Net receipts.	Ditto per mile.	% Net receipts / Capital expd.	Car miles.	Passengers carried.
			£	£	£					
Birmingham	25	Electricity, Steam, Cable, Horses	...	...	154,684	37,715	1,508	...	2,655,802	26,277,089
Leeds	14	Steam, Horses	200,222	14,301	44,691	4,623	330	2⅓	875,437	18,282,304
Edinburgh	18½	Cable, Horses	377,629	20,412	204,608	28,046	1,516	7⅔	1,584,031	15,425,666
Glasgow	30¼	Horses	489,201*	15,180	260,866	45,325	1,498	9⅓	4,702,089	51,506,451

* Of this sum £390,666 has been expended by the Glasgow Corporation itself, including an item of £52,247 on legal and Parliamentary expenses.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 9th.

Physical Society.

5 p.m. Annual General Meeting. The following Paper will be read: "The Viscosity of Liquids," by O. G. Jones.

Northern Society of Electrical Engineers.

8 p.m. Ordinary Meeting at the Palatine Hotel, Manchester. The following Paper will be read: "Blackpool Electricity Works," by J. Hesketh.

Junior Engineering Society.

8 p.m. Meeting at the Westminster Palace Hotel. Paper to be read and discussed: "The Construction and Working of Electro-motors," by A. H. Dykes.

Royal Institution.

9 p.m. Evening Discourse on "Fortuitous Variation in Animals," by Prof. W. F. R. Weldon, F.R.S.

SATURDAY, February 10th.

Royal Institution.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

MONDAY, February 12th.

Society of Engineers.

7:30 p.m. Ordinary Meeting at the Town Hall, Westminster. Distribution of Premiums, by Mr. W. A. McIntosh Valon, Past President, and Inaugural Address by Mr. G. A. Goodwin, President for the year 1894.

Society of Arts.

8 p.m. Cantor Lecture: "The Detection and Measurement of Inflammable Gas and Vapour in the Air." By Frank Clowes, D.Sc.

TUESDAY, February 13th.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Transport of Petroleum in Bulk," by Boverton Redwood.

WEDNESDAY, February 14th.

Society of Arts.

8 p.m. Ordinary Meeting. "The St. Pancras Electric Light Installation," by Prof. Henry Robinson, M.Inst.C.E.

FRIDAY, February 16th.

Royal Institution.

9 p.m. Evening Discourse: "Bacon's Key to Nature," by Prof. Nichol, M.A.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices:
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

THE MISCALCULATION OF MAINS.

When engineering practice is found to differ in two countries, we must assume that the conditions are unlike, or that one is enjoying a higher degree of development than the other. A case in point is the elaborate calculation of conductors for electrical supply. In Germany this has received the careful attention of several mathematicians, and the art of solving the problem has arrived at a high degree of perfection. To many engineers who are actually engaged in proportioning the mains for new or for existing systems of supply, these niceties of calculation appear somewhat superfluous. The diagrams and calculations which Prof. FORBES has more than once described, serve to elucidate certain abstract principles rather than to guide engineers in the choice of section for any particular service main, or even in the selection of a feeding point. The whole question turns on the data upon which such calculations are to be based. We are informed that it is recognised by German engineers that it is impossible to predetermine the demand, but that by comparison between the character of the locality and the existing distribution of gas lights, they arrive at a scheme which is considered worthy of some tedious research. Promoters of electric supply undertakings are well aware of the difference between the results of a preliminary canvass, the

original system of mains, and the network that is actually employed after the experience of a year or two. We can well imagine that in a socialists' Utopia, where each man enjoyed a fixed "living" income and lived rent free, a supply network might be pre-determined. The problem, indeed, would be easy, for everyone would demand electric supply as a "right." The design and arrangement of feeders is much more calculable; but even here the necessity for guesses as to the probable demand renders any exact statement of the problem impossible; after supply has commenced, the demand is often found to grow in unexpected districts and to languish in streets of which great things had been expected.

Recognising, of course, that the conditions of electric supply in this country differ from those of Germany, we are not prepared to admit that English engineers exhibit ignorance or carelessness in failing to pay much attention to these calculations. They all know Lord KELVIN's law well enough, and most of them are acquainted with the further considerations of Profs. AYRTON and PERRY. Shrewd judgment and experience rather than algebra are required in determining the section of a feeder, for the mere C^2R losses present but a trifling difficulty compared with the forecasting of the probable future load, and the excess of copper which must be laid to-day in order to meet the conditions which may be expected a year or two hence. The study of existing gas supply cannot of course be ignored, but who can judge of the character of a locality? Unless it can be expressed as a single coefficient it is of little use. Will future treatises on electric supply give us the proper constants for Piccadilly, London, and for Piccadilly, Manchester, and enable us to compare Belgrave-square and the Broomielaw? Nice calculation of mains is no doubt a pleasant pastime for mathematicians; even the resistance of a stranded conductor presents several agreeable and perfectly useless problems, useless because it is impossible to assign values to the constants. But besides the considerations which depend on the mere geometry of conductors, such as the selection of the best site for a supply station by calculating the centre of gravity of all the proposed lamps, and the Kirchhoff relations of the currents in the supply network, there is no end to the complications when losses and their cost come to be examined. There is reason to believe that the scant literature upon the subject in this country is partly due to the existence of Edison's feeder patent. Although it is generally supposed that no claims will be enforced, more than one engineer declines at present to call certain conductors "feeders"; and men who have been practically engaged in designing systems of mains are not likely to be very communicative about their work until after September 24, 1894.

Losses in feeders must be separated from losses in networks. The economic examination of losses in networks ought to be neglected for the simple reason that these ought to be negligible. The requirements of the Board of Trade are satisfied "so long as the pressure does not at any point vary more than 3 per cent. from the corresponding pressure in the case of a general supply at low pressure, or 2 per cent. in the case of a general supply at high pressure, unless changes in pressure recur so frequently as to cause unsteadiness in the supply." Well-managed companies succeed, for their own credit, in keeping well within these limits; and if two feeding points were kept at 103 volts, and the midway customer got only 97 volts, these six lost volts would be a misfortune. It would not be proper to calculate the lost watts, and debit the cost of the energy wasted per annum against the interest on the supply conductors. Let the loss be reduced, if the company can afford it, either by shifting a feeding point or by drawing in more copper. This is where common sense comes in. When once an ardent mathematician gets entangled in network-problems, he will not stop until he has debited a proportion of the interest and depreciation of the chimney stack to the watts wasted in the station ammeter.

The steady growth of electric supply brings into prominence questions of adaptation of an existing system of conductors to a gradually changing load. The strength and steadiness of this growth in London is clearly shown in the diagram which will be found in another column. The changing or shifting of the load is felt chiefly in the extensions of the mains in new streets. If the load merely increased in streets already supplied, the loss on the feeders would rise until it became necessary to draw in more copper, and the loss on the network would rise until the Board of Trade limit was reached, unless the supply company for their own reputation increased the conductors. A simple case of that kind might be calculated in great detail, but the addition of new streets, being those streets in which business is promised, or, on rare occasions, streets which lie in the route to new business, altogether upsets previous calculations; and though calculation might show whether a new feeder, a branch feeder, or the shifting of an old feeder would be the best course to adopt, business considerations would generally carry more weight with the engineer than mathematics, and as the chances of business are beyond the powers even of ellipsoidal harmonics, mathematics must give way to sound common sense.

REVIEWS.

British Locomotives: their History, Construction, and Modern Development. By C. J. BOWEN-COOKE. (London: Whittaker and Co.)

This attractive work ought to meet with a welcome from everyone interested in the railway locomotive. It is mainly written for the outside public, but will, it is clear, be useful to the engineering student and to railway men, be they on the locomotive staff, drivers, or firemen. From the earliest road carriage down to the "Empress Queen," exhibited at Chicago, the author gives the history of the locomotive; every part is clearly and concisely described, and even the duties of drivers and firemen are set out in a readable form. For the professional reader many of the chapters on construction, and particularly the ones on valve motion and brakes, will prove interesting. There is perhaps a little too much of the London and North-Western and Mr. Webb in the book, and too little about the North-Eastern compounds, and we should have liked a chapter devoted to the great work done by private engineering firms, but one cannot have everything, and it must be confessed that Mr. Bowen-Cooke has made a good book. The work is well and plentifully illustrated from sketches and drawings by Messrs. C. E. Jones and R. A. McLellan, and reproductions from official drawings and photographs of engines built by the leading lines. Many of the twenty odd drawings of the earliest engines will raise smiles when contrasted with pictures of the latest types.

Helical Gears. By A FOREMAN PATTERN-MAKER. (London: Whittaker and Co.)

The pattern making and moulding of helical gears is discussed in this volume, with a rather inadequate introduction on their design. A couple of pages only are devoted to the question of the strength of helical teeth, but no definite information is given. The limits of accuracy which the author expects do not seem to promise success with helical gear. It is generally admitted that unless of first-rate work, little or no advantage is offered over ordinary gear. Mr. Longridge's feathered wheel, to accommodate side thrust, is alluded to; but the importance of high accuracy to minimise end thrust is not insisted on with sufficient emphasis.

Digitized by Google

Modern Shafting and Gearing. By M. P. Bale. (London: W. Rider and Son. 1893.)

We have here a little book giving, in a condensed form, the author's recommendations for the design and management of shafting and gearing. The writer is too sparing of his materials—his engineering materials, we mean—he does not use a sufficiently high factor of safe working. The table of shafting puts too great a load on the shaft; and the practice, if followed, would lead to vibration and unsteady running, with all their consequent evils. The same remark applies to many of the writer's other rules for gearing design.

The Electric Transformation of Power. By Philip Atkinson, A.M., Ph.D. (London: Crosby Lockwood and Son; and New York: D. Van Nostrand Company. 1894.)

Treating the subject mainly from an American point of view, this work is a short and descriptive account of the application of the electric motor to mechanical operations. The introductory chapter is on "Definitions," and makes a by no means happy commencement. We are told, for example, that "electric potential is that condition in bodies which represents the relative electric energy manifested by them. When the quantity of this energy differs in bodies associated together, those in which it is greater are said to have positive potential with respect to those in which it is less, and the latter to have negative potential with respect to the former; but when it is equal in all, they are said to have zero potential with respect to each other." With far less cudgelling of the reader's brains, and far less printer's ink, it would have been easy to give the correct version of the definition of potential.

Chapter II. is on the "Principles of the Electric Motor," and is well written; but it contains nothing new either in the subject-matter or its treatment. Chapter III. describes a number of "Stationary Motors," mostly of American design; and the following chapter discusses their application to various purposes, the special details necessary for adaptation being particularly described. The chapter on "Electric Railways and Railway Motors" covers the ground of the various systems in a brief, descriptive style, but the treatment is too condensed to be of much real value. The American trolley system receives the largest share of attention, but some paragraphs at the end are devoted to conduits and battery cars. A short chapter on "Central Stations" concludes the work, which is copiously illustrated throughout.

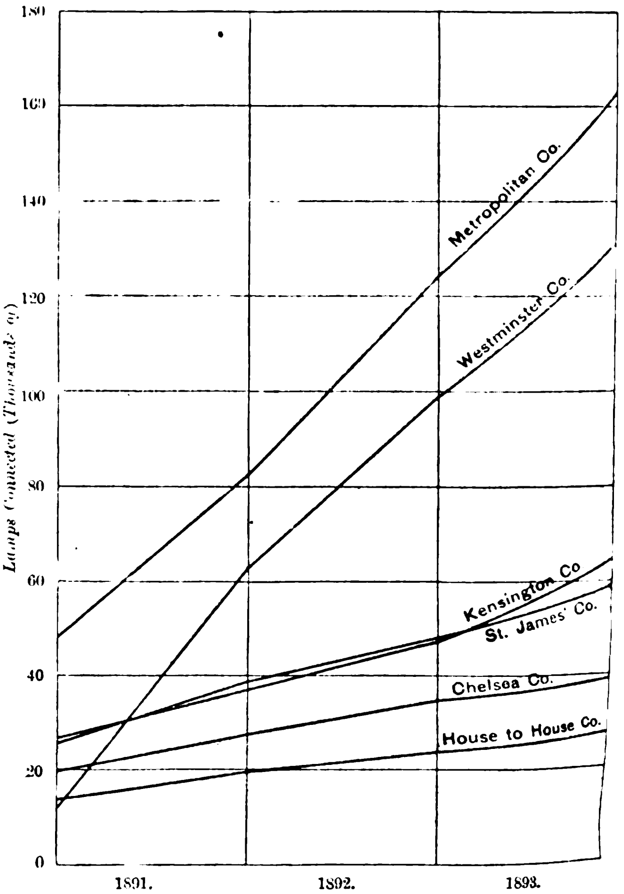
Continuous-Current Dynamos and Motors. By F. P. Cox, B.S. (New York: The W. J. Johnston Company. 1893.)

This work is offered as an elementary treatise for students. The electrical parts are treated on the lines usual in elementary books on such subjects, and call for no special comment. But we do not quite see the necessity for sandwiching two chapters on "Indicator Diagrams" and "Steam Engine Calculations" between the electrical sections. Even in a work for practical dynamo users such a plan might be deemed irrelevant, but elementary students at least may expect to be supplied with the various sections of their studies in separate suitable treatises. Moreover, although it is quite right to save these beginners from the obstacles presented by advanced mathematics, it is not just to offer them a popular version in place of exact science. The statements on page 17, to cite one of numerous cases, are misleading for this very reason: "When a wire sweeps across a magnetic field the lines of force, being elastic, tend to wrap themselves around the wire. But when these lines are created around a wire there will be a current of electricity in the wire. Therefore . . . . . a difference of potential or pressure is created between the ends of the wire." The principal mistake in this sentence is the statement that a current would be induced, whereas only an electromotive force might be induced. Another mistake lies in the inference that *because* there is a current, therefore there is a difference of potential; for the former might exist without the latter, or the latter without the former. Still another error arises in the subsequent sentence, in which, by means of the ubiquitous hydraulic analogy, it is attempted to show that the difference of potential is a fall in the direction of the current, whereas, in a wire in which a current is being induced, the difference of potentials, if any, is opposite to the induced current.

We select this example of the author's treatment of his subject, not because we wish to be hard on him for any single blemish (for we do not), but because we believe this sentence we have chosen to be typical of the general treatment throughout the book. The matter selected for this little work is well chosen, and it is dealt with in an interesting and simple manner, which is well adapted to the needs of an amateur who makes no pretence to serious study of the subject.

THE INCREASE OF ELECTRIC LIGHTING IN LONDON.

It has been suggested that the falling off of the revenue of the St. James' and Pall Mall Electric Supply Company during the past year was due to the "saturation" of their district. There are two chief quantities which may tend to a saturation or, as it is called by mathematicians, an approach to an asymptotic

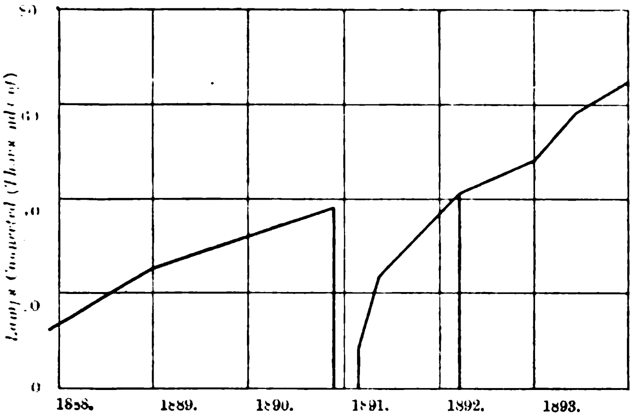


limit. The one is the total number of lamps fixed, the other the revenue. The latter we will leave for the present, but hope to return to it when the 1893 accounts of the London companies are before us. The growth of the total number of lamps can be obtained from the tables of statistics published in our New Years' numbers, and from the reports of the companies. Discarding events prior to 1891 and the doings of companies who have only begun work since that date, the diagram, Fig. 1, shows very clearly the steady and very satisfactory increase of business of six companies.

The average rate of increase seems to be about ten thousand lamps per annum for each Company, if the Westminster and Metropolitan Companies be excluded. It is to be noticed that these two great concerns have three and four supply stations respectively, and that the steepness of the lines is roughly three and four times that of the average of the other companies. In other words, if separate stations had been taken, nearly all the lines would have been closely similar. A

slight increase of steepness in the Kensington and Knightsbridge line is observable, and a slight decrease in that of the Chelsea Company. The latter does not indicate any approach to saturation, for these features are explained by the transfer of part of the district and of the business of the one company to the other. Had this transfer not been made, the lines would have been almost exactly stra ght. A mathematically-minded man might say that the tangent of one of these lines to the horizontal axis is a function of the product of the richness of the district into its area, and he would proceed : let θ be the angle and any instant, and ρ the richness of the area at that instant, &c., &c. We do not propose to follow him nor to pretend to construct a formula by which the point of saturation and the date at which it may be expected can be calculated. Suffice it to say that not in the poorest nor in the most prosperous district is there as yet any sign of that drooping towards the horizontal, which is, of course, some day inevitable.

The London Electric Supply Company has a diagram to itself, not only because it would somewhat confuse the others if plotted with them, but because the historical tale it tells deserves it. Fig. 2 shows the lamp connections of the London



Company as found by careful examination of back numbers of *The Electrician*. We have no information of the Grosvenor Gallery business prior to Christmas, 1887. The line begins here, and rises briskly during 1888, but the plant was becoming overloaded, and during 1890, while the dynamos were being removed to Deptford, fresh business had to be refused. On November 15, 1890, the Grosvenor Gallery substation was burned, and no sooner was another set of transformers hurriedly repaired and connected than they broke down, and the supply was stopped altogether. On February 16, 1891, it was resumed, and 9,000 lights were at once connected. Additions went on well until March 10, 1892, when owing to a fire in one of the South-Eastern Railway Company's arches, all four of the Ferranti mains were injured. The supply was completely stopped for only a few hours, but the result, as shown by our curve, was a distinct shaking of confidence in the supply. Since the beginning of last year, however, business has been excellent, and the rate of increase during the end of 1891 has been regained. Curves showing the increase of lamps month by month or week by week would be of interest. We have such a curve before us, for one company and for one year. It has a gentle curvature, flattening in the spring and becoming steeper in the autumn. To ask the secretaries of companies to send us data for a set of such curves would probably be to trespass too much on their time.

TELEGRAPHIC COMMUNICATION BETWEEN ENGLAND AND INDIA, ITS PRESENT CONDITION AND FUTURE DEVELOPMENT.*

BY E. O. WALKER, C.I.E.

My plea for bringing this Paper before you lies in the fact that I have spent many years in the telegraph service of India, that I have been witness of the gradual growth of its traffic, and of the careful building up of its telegraphic communications with other countries, and that in dealing with telegrams in such important places as Bombay, Calcutta, and Madras, I have been brought into contact with the commercial publics which have the larger interests in foreign telegraphs, and to whom the cost, as well as the accuracy, rapidity, and regularity of dispatch of messages are so important ; that I have been privileged to know, perhaps better than those outside the telegraph service of the State, what can and should be done to meet the wants of the public in these respects. The time seems to have arrived when it may be useful to review what has been done in the past towards bringing India and the United Kingdom into closer community of interests by the telegraph, and to offer some suggestions which may lead to the telegraph becoming a more important factor in trade, by making its use cheap.

The telegraph soon made its influence felt among commercial communities. It was being found that it made trade brisk, by aiding a quick interchange of commodities ; and profitable, by preventing the accumulation of large stocks through the early information it afforded of the state of the large markets ; and rendered trade safe, by strengthening the control by Government of the foreign affairs of the State. It was beginning to be realised that the material welfare of a country would, therefore, be largely dependent in the future upon its connection by telegraph with the foreign territories with which it traded.

In 1854, Mr. Gishorm* put forward a project for a cable from the Dardanelles to Alexandria, as a first step towards establishing communication with India. A concession was obtained from the Porte, but the scheme fell through. At this time, although early in the history of submarine telegraphs, some were found to favour the cable route exclusively ; while others placed their faith entirely in overhead wires, save in localities where frequent damage to such lines was to be apprehended. Events have proved that India has benefited by this difference of opinion, since it has secured to her two good working routes. In 1855, advocates of the overland telegraph formed the European and Indian Junction Telegraph Company, to erect telegraphs from Alexandretta, on the coast of Palestine, to Korna, at the junction of the Euphrates and Tigris ; but Turkey eventually refused the desired concession. It must be confessed that the fears as to the stability of our overland communication were, in some respects, verified, but, fortunately, did not at the time so far prevail as to frustrate the scheme. All this would be far from encouraging to those who would rely upon overhead wires, did we not know that by firm control of the people through whose territories they pass, by incessant attention to the strengthening of the lines, and by the elimination of weak points, interruptions such as I have described have been rendered rare, and further that, owing to land lines being cheap, we can afford to have two or three alternative ones with plenty of wires, for the same cost as our submarine cable.

An influential section of the commercial community favoured a submarine telegraph to India, and in 1857 the Red Sea Telegraph Company was formed,† with a guarantee from Government, to lay a cable from Suez to Kurachi *viâ* Aden, in connection with a direct cable from Malta to Alexandria, projected by the Anglo-Mediterranean Telegraph Company. It was true that the sea route to India would require 5,000 miles of cable, but the supporters of the scheme thought that the cable once laid would be lasting, that the liability to interruption in war and times of political disturbance would be much less than by the overland route by Turkey or Persia. For an enemy to grapple and raise cables for the purpose of cutting them would require not only a knowledge of their exact positions, and a ship specially fitted, but above all, would take up too much time. In 1859-60 Messrs. Newall laid the Red Sea cable at a cost of £800,000. The bold scheme, unfortunately, ended in total failure ; the cable was never worked throughout, and Government became involved in heavy pecuniary obligations. The manufacture and laying of cables were not so well understood then as was the case a few years later. The cables‡ were not, as was subsequently found to be necessary, tested for insulation under water from the time of manufacture until paid out from the ship, and, in the present case, are said to have been laid too taut, so that they were suspended across the inequalities in the ocean bottom, instead of being slack enough, as they should be, to lie evenly with the irregular contour. Then, again, the route had not been, as is invariably done now, carefully surveyed, and the consequence was that damage was done by the cable chafing on the coral reefs. Further, the Red Sea cable was covered externally with light wire guards only, unprotected by bituminous compound. These wires, which should give strength to the cable, rusted so quickly in the intensely salt water, that in a short time the cable could not be lifted for repairs. In the idea, probably, that signalling would be accelerated by so doing, the cable was divided into short sections, touching at Cassiri and Souakin in the Red Sea, and at Hellania and Muscat on the east

coast of Arabia. The course taken lay through much shoal water, notoriously bad for a cable. The failure of this cable and of the first Atlantic one, which worked for only one month, which involved a loss of £450,000, greatly discouraged further enterprise. Sir James Anderson summarised the causes which led, in the early days of submarine telegraphs, to the failure of cables, as follows :—(1) Inexperience of insulating material ; (2) impurity of the copper conductor ; (3) the mechanical difficulty, in keeping the copper wire in the centre of the insulating medium ; (4) laying cables from sailing ships in tow of steamers. He says that experience disproved also the notion that there was little motion in the sea at a depth of 100 fathoms. On the contrary, the Falmouth cable was moved, chafed, and destroyed at a depth of 500 fathoms ; and the Channel Islands' cable suffered in the same way. He mentions, likewise, the injuries caused to gutta-percha by the teredo borer even at a depth of 1,200 fathoms, an enemy which in more recent years has become well known, and to guard against which brass or copper tape is spirally wound round the core of cable.

To return to the overland route, the line from Scutari to Baghdad had been begun in 1859, under the direction of Col. Biddulph and Lieut. Houldsworth, and was carried on to Baghdad by Messrs. Carthew and McCallum. There was some doubt as to whether a line could safely be carried from Baghdad to Basra, owing to the troublesome character of the tribes in that locality, and it was not until October, 1863, that Turkey agreed to complete the line so as to meet the Indian Government cable projected from Bushahr to Basra. Meantime, in 1861, to overcome this difficulty, the Shah of Persia was approached by the Indian Government with a proposal to construct overhead telegraph lines from Bashahr to Khanikui, on the Turkish frontier, to meet a Turkish line from Baghdad. Persia did not at first welcome these negotiations, nor did Turkey desire to be united to a Persian telegraph system. Col. Patrick Stewart failed—early in 1862—to induce Persia to come to terms, but, at the close of that year, the Shah determined to erect the proposed line at the expense of Persia. Sir F. Goldsmid graphically describes in his book, "Telegraph and Travel," the difficulties met with by the working parties. However, persistent effort at length overcame such difficulties, and the line was completed in October, 1864. Mr. H. I. Walton, in constructing the land lines from Kurachi to Guadur, at the same period, had no easy task. For years they worked badly, owing to the insulators becoming coated with salt and fine dust, a common occurrence with coast lines in the tropics, but the insulators now used, which have a rim containing oil, appears to have improved communication.

Colonel Patrick Stewart laid the first Persian Gulf cable, from Guadur to Bushahr and Fao, in November, 1863, and it was completed to Kurachi in 1864. This was a gutta-percha cable* made by Henleys, 1,200 knots in length, and cost £411,751. The present electrician of the Indo-European Department considers that it was one of the best ever made. In connection with the work the name of Mr. F. C. Webb, of the staff of Messrs. Bright and Webb, who was electrician, should be mentioned. This cable, together with the Hooper's india-rubber cable, laid in 1869 from Bushahr to Jask, has had many accidents. Friction on the rocks, and consequent chafing, decay of the iron guards, the attacks of the teredo, ships' anchors in shallow water, and fish bites on the core, where the guards had rusted off, have given much trouble. Once an earthquake buried part of the cable ; on another occasion a swordfish attacked and pierced the cable ; and one instance was found where a whale got its tail entangled in it and produced a loop or twist. Up to 1892, the capital outlay by the Indian Government on the land lines to Jask and the Gulf cables, with the signal offices, amounted to £1,151,507. That Government had performed its share in establishing communication with Europe by April, 1864 ; but owing to delay in uniting Baghdad with Basra in Turkish territory, communication between Kurachi and London was not established until February, 1865, when a message took eight and a-half hours in transit. Sir F. Goldsmid describes as wretched the service on the European lines, and for five years, by conferences and negotiations with the administrations concerned, endeavours were made to supply wants, to remedy failings, and to remove obstacles. Even in 1872 Col. Champain, the Director-in-Chief of the Indo-European Department, describes the "Turkish route as hopelessly behind the requirements of the age." Messages to and from India had occupied 24 and even 48 hours in transit. The multiplicity† of routes to Constantinople, *viâ* Paris, Berlin, and Frankfort, led to confusion, and to the order of telegrams being inverted. There were three re-transmissions in Turkish territory, effected often by ignorant and over-worked Greek and Armenian clerks, and three more between Fao and Kurachi, and those who are intimate with telegraphy will readily appreciate the liability to loss and error that these re-transmissions would involve. The line through Russia *viâ* Tiflis to Teheran, by which Anglo-Indian messages could travel, was also wretchedly organised (1865), Russia being unwilling to spend money on it, and the clerks at the offices *en route* being ignorant of English.

* "History of the Persian Gulf Cables," by Passman.

† "Existing and Projected Telegraph Routes to India," by Sir J. Andrew.

In 1868, a telegraph congress was held at Vienna to fix tariffs and to arrange with the different powers concerned to regulate the Indo-European service across the continent, but even after settling upon eight Continental routes, five for the Indo-Ottoman and three for the Russo-Persian lines, the service to and from the East still remained indifferent. In January, 1870, the delay by the Indo-European route * was over 24 hours, the difficulty of keeping the lines in order being described as worse than on the Turkish route. Between Teheran and Bashahr the line is said to have been chronically interrupted.

With the pioneer systems of international telegraphs, and especially those in the East, it was easy to find fault. No doubt the same experiences gained then will be reaped by those who have to carry out the Trans-Continental African telegraph, and any similar scheme in primitive and barbarous countries. But the commercial world, having tasted—by means of the pioneer lines—of the advantages of the telegraph to India, now bestirred itself. It was felt that an irregular service was worse than none at all. The success of the Atlantic cables of 1865 and 1866 had proved that an ocean cable, when carefully treated, could be relied upon as a permanent and regular means of communication, and showed, what was of immense importance in stimulating telegraph enterprise subsequently, that a heavy cable could be picked up from the ocean bottom and be repaired. The Telegraph Construction and Maintenance Company applied to Government for a guarantee towards the expenses of a cable from Suez to Bombay, 3,654 knots in length, estimated to cost, with stations and instruments, £1,100,000. It was pointed out that the necessity for taking lines through desolate countries and among semi-barbarous races would be avoided, and that, by the experience gained in the case of the Atlantic and other cables, the depth of the ocean was shown to be the best guarantee for the permanence and security of the wire. As to the objection then raised, that part of the proposed circuit would lie in Italy and France, it was explained that the traffic was guarded by conventions, and the line in Italy worked by English clerks. The cable from Alexandria to Malta was already laid, and the Company was even prepared to lay one from Falmouth to Malta to obviate the possibility of disturbance. But Lord Cranbourne, then Secretary of State for India, rejected the proposal that the Indian revenues should be applied to the guarantee, and pointed out that a large amount had been spent on the Persian Gulf cables to co-operate with other countries in completing the land line to India. Again, in July, 1867, the Anglo-Indian Telegraph Company was formed for a similar purpose, with Captain Sherard Osborne as Managing Director. In April, 1868, the City of London again renewed the attack. A memorial, signed by the Lord Mayor and many of the merchants of London, advocating the cable, was presented to the Secretary of State. No satisfactory reply was received, the recollection of the obligations assumed for the Red Sea cables being then too lively.

There were those who foresaw that in times of peace, at all events, the overhead lines, if well administered, would go far to meet commercial needs, and, thanks to an eminent firm of telegraph engineers and manufacturers, Messrs. Siemens and Halske, of Berlin and St. Petersburgh, a concession for a term of 25 years was obtained from the Russian, Prussian, and Persian Governments, for the purpose of uniting Teheran and the lines of the Government of India with those of North Germany, which Prussia agreed to erect. England and the Continent would thus work direct, through a specially-reserved circuit, to India. The system was to be under English management. Out of this arrangement grew the Indo-European Telegraph Company, formed in April, 1868, with a capital of £450,000, which has, now that the difficulties of the initial work have been overcome, provided an excellent service to and from India, *viâ* Lowestoft, Emden, Berlin, Odessa, Kurtch, and Teheran, in conjunction with the Indo-European Government department, which controls the circuits from Kurachi to Teheran. The improvements in the latter are largely due to the efforts of Mr. Ffinch, for the last 18 years Deputy-Director of the Persian Gulf section ; of Major Wells, R.E., occupying a similar position in Persia; and of their efficient staffs. The overland lines have in the past suffered both from wilful damage and from snowstorms, and, as I have mentioned above, the Persian Gulf cables give no rest to those charged with their maintenance; but the constant vigilance of the officials of the two administrations has certainly been rewarded by the speedy and accurate service now afforded.

To those who came forward in the years 1868 and 1869 to subscribe £2,000,000 for laying cables from England to India, the gratitude of both countries is due. Had the scheme failed it is most probable that the telegraph service would still have remained

Digitized by Google

slow and irregular; but the issue being successful, the healthy stimulus of competition came into play. I believe that Sir John Pender—whose name is so well known in the cable world, and under whose able direction many of the cable systems have flourished—Sir R. Glass, Sir George Elliot, Sir Daniel Gooch, Sir James Anderson, and a few others, subscribed £400,000 of the required capital. The Falmouth, Gibraltar, and Malta Telegraph Company was formed in July, 1869; the Anglo-Mediterranean Company in May, 1868 (for a cable from Malta to Alexandria); and the British Indian Telegraph Company, for uniting Suez and Bombay, in January, 1869. The total length of the cables was 6,456 knots. The "Great Eastern" left Portland on November 6, 1869, with over 2,000 miles of cable, accompanied by three other steamers, and by March 15, 1870, Bombay was in communication by cable with England. The various companies above referred to were amalgamated in November, 1872, under the title of the Eastern Telegraph Company. Communication was successful from the outset. The marvellous skill shown in contriving appliances by which the retardation caused by electrical charge and discharge of a cable could be overcome was such, and the instruments by which feeble undulations could be recorded so delicate, that even in the year 1872 the cable from Aden to Bombay (1,818 knots) could convey messages more quickly than could a wire of less than half that length from Bombay to Madras. As an instance of the celerity with which a telegram could be received from England, I may mention that on the evening of Derby Day, 1872, when a few of us were watching for the news in the Calcutta Telegraph Office, Reuter's telegram, with the name of the winner, arrived a few minutes after the horse had passed the post. The success of the cables, financially, was at once secured; in 1872 a dividend of 6 per cent. was paid on the capital stock. The service has been rendered still more perfect since then by the duplication of the cables throughout, and by a third from Suez to Bombay, laid within the last three years.

Yet another company for carrying the telegraph to the East was formed in 1869—the Great Northern—to connect England and France with the north of Europe, China, and Japan, with a capital of £1,500,000. Its land lines cross Russia and Siberia to Vladivostock, whence a cable proceeds to Japan, and another to Amoy. This telegraph, which affords another route to India, by way of Hong Kong and Singapore, through the cables of the Eastern Extension Telegraph Company, has also been a decided financial success. In 1874, 5 per cent. was paid on the capital, and larger dividends have been earned since. At the present day there is another line through Siberia, connecting China and Russia, and one projected, which will be the shortest route from Pekin to Europe.

(To be concluded.)

NOTES OF A TRIP TO THE UNITED STATES AND TO CHICAGO, 1893.*

BY W. H. PREECE, C.B., F.R.S., PAST-PRESIDENT.

(Concluded from page 359.)

Rates.

The rates or rentals demanded from the various subscribers differ very much in the States. At Buffalo they charge a toll rate on each talk; they do not demand an annual rental; they simply demand a minimum amount of business per annum. This rate in Buffalo is 10 cents for five minutes' talk, and they have adopted a system of charging one-fifth of this rate for each extra minute beyond the five. The rate in San Francisco is a small annual rental for each installation, and 5 cents for each talk. A somewhat similar plan is in use at Milwaukee. But, with these three exceptions, the toll system has not found favour in the States, and at every other exchange an annual rental is demanded. The American Bell Telephone Company are now considering the advisability of limiting the time for talks to three minutes instead of five, of reducing the minimum toll in proportion, of making additional charges for each minute *pro rata*, and of considering a fraction of three minutes as equivalent to the whole time.

The rates vary, and are, as will have been seen, very high; but although the enterprise is in the hands of private companies, it must be noted that they have great difficulties to contend with. In a place like New York the rents and the cost of buildings is excessive. In one small exchange they pay no less than $7,000 a year rental for one floor. Taxes everywhere are enormous. Not only are they taxed by the State, but they are taxed by the municipalities. Way-leaves are excessive. In New York alone they have to pay to the Company controlling the underground conduits no less than $80,000 per annum way-leave—$8 per renter for way-leave alone. The distances, too, that they have to carry their underground system in New York, in Philadelphia, and in other places are very considerable. They have been forced by municipal action to go underground. In the face of these restrictions no comparison between rentals in New York and those paid in this country can be made. The amount of the average rental in London scarcely exceeds £15 per annum. The average amount of rental throughout the country on our Post Office system is £9. 10s., but in New York subscribers have to pay up to £50 per annum.

* Paper read before the Institution of Electrical Engineers, January 25th.

I give below, in tabular form, the rentals charged in 25 of the chief cities of the States:—

Standard Yearly Rates for Subscribers.

* Does not include express subscribers. With express, 72 inhabitants.

Digitized by Google

It will be seen how very much these places vary. In Providence, for instance, with a population of 132,146, we find one subscriber to each 45 persons; while in Philadelphia there is one to every 289 only.

In 10 of the principal towns of our own country the results are as follows:—

—	Population.	Subscribers in exchange.	Average No. of inhabitants to each exchange subscriber.
London	4,263,294	6,700	636·3
Liverpool	513,790	4,500	114·1
Manchester	510,998	2,300	222·1
Glasgow	669,059	3,200	209·0
Edinburgh	264,787	900	294·2
Plymouth	85,610	300	285·3
Birmingham	483,526	1,200	402·9
Leeds	375,540	1,300	288·8
Hull	204,750	400	511·8
Newcastle	192,205	1,300	147·8

The telephone in the United States is essential to the business man, and its price is compared with that of an office boy. Labour in the States is expensive, and an office boy costs more than a telephone subscription. The present generation in America has grown up with the telephone. It has become a factor of business, and absolutely essential to the transaction of that business. Its use has passed its climax; it has reached its normal stage. There is no touting for business; business comes. Every new office must have it. The working is excellent, and they are alive to the necessity of maintaining its efficiency at the very highest point. Education is complete, not only of the staff, but of the customer. The apparatus itself is being perfected. Uniformity of practice is being introduced under the operation of the paternal control at Boston, and the influence of technical education and of technical institutions is being felt everywhere. I find a group of highly educated, clever young electricians being engaged and encouraged by the telephone companies. New blood is being introduced, and great zeal and activity is shown.

III.—The Electrical Congress.

Two Congresses were held in Chicago—the one, a general one, to which all electricians were invited; and the other, called "The Chamber of Delegates," to which nominees from the different Governments were sent. The latter was the more important of the two, but each secured considerable attention, and they were distinctly great successes. The following extract from an American technical journal very fairly summarises the results:—

"The Chicago Congress.

"The much-talked-of International Electrical Congress is now a thing of the past. Its record may be briefly summarised by saying that the attendance was good; that it was truly international: that there were just about enough papers; that some good work was done; that the social features were enjoyable; and that, while the general management left much to be desired, the Congress itself was a success—not quite as grand a success as we should like to have seen, but, nevertheless, a success. Among the Papers read were a few which created unusual interest, and some which will, doubtless, become standards of reference. The Papers and discussions were of such a character that the published volume of the proceedings will be interesting reading, and will become a book of reference. The foreign attendance was such that the Congress became truly an international one. Among the foreign countries represented England took the lead in numbers, and especially in Papers read and in the discussions. Germany and France came next. That it was an international assembly was shown by the fact that the French language was freely used in Papers and discussions, the only reason why German was not used being that educated natives of that country almost always understand and speak English. Thanks to a few energetic, experienced, and willing members and exhibitors, the social features were not entirely omitted. The social events that did take place were enjoyable, and will be long remembered by those who took part."

The Congress met on August 21st, at least 500 being present. Prof. von Helmholtz was appointed hon. president, Prof. Elisha Gray chairman. Each principal European country had a vice-president, and I had the honour of being selected to represent England. The Congress was divided into three sections:—(A.) Pure theory. (B.) Theory and practice. (C.) Pure practice. Some excellent Papers were read, and good discussions ensued. The most prominent subjects dealt with were the transmission of power to great distances, and general preference was shown for alternating current systems. The work being done at Niagara excited general interest, and some of us visited these works afterwards, with great profit and pleasure. Prof. Ayrton read a very able Paper on "The Variation of Arc Lamps," so much used in America; while much interest was created by the reading of a Paper by Prof. Silvanus Thompson on "Ocean Telephony," a possibility in the future. My Paper on "Signalling through Space" also created much interest. Perhaps the most useful result of the Congress was the bringing together of such an international mixture of electricians, making friendships, allaying jealousies, and breaking down national prejudices. Electricity is the only branch of science which has but one language, and it is now quite cosmical in its character. Congresses do infinite good in promoting friendliness among nations.

Chamber of Delegates.

The object of this meeting was really to consummate the work done by the British Association and by the Board of Trade, and to secure the official sanction of the United States Government to the units selected and adopted in England. This was done, and the report of the Chamber gives international support to the proposed legalisation of the ohm, volt, farad, ampere, watt, and joule, as defined by the Committee of the Board of Trade. There is no doubt that all European Governments will now accept these decisions.

A new unit was adopted, viz., the "henry," a unit of induction, which was sometimes called the "quadrant," as defined in Paris in 1889, and sometimes the "secohm," as proposed in England. The acceptance of the name "henry" pleased the Americans very much, for their nationality has hitherto been unrepresented among the celebrated electricians whose names have been applied to the standards of electrical measurements. Germany, Italy, France were represented by Ohm, Volta, Couloumb, and Ampere; while England absorbed no less than three, viz., Faraday, Watt, and Joule. America has now her Henry, and is satisfied.

The following is the official report of the proceedings:—

"*Resolved*,—That the several Governments represented by the delegates of this International Congress of Electricians be, and they are hereby, recommended to formally adopt as legal units of electrical measure the following:—As a unit of resistance, the *international ohm*, which is based upon the ohm equal to 10^9 units of resistance of the C.G.S. system of electro-magnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass, of a constant cross-sectional area, and of the length of 106·3 centimetres.

"As a unit of current, the *international ampere*, which is one-tenth of the unit of current of the C.G.S. system of electro-magnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, and in accordance with accompanying specifications, deposits silver at the rate of 0·001118 of a gramme per second.

"As a unit of electromotive force, the *international volt*, which is the electromotive force that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampere, and which is represented sufficiently well for practical use by $\frac{1000}{1434}$ of the electromotive force between the poles or electrodes of the voltaic cell known as Clark's cell, at a temperature of 15°C., and prepared in the manner described in the accompanying specification.

"As a unit of quantity, the *international coulomb*, which is the quantity of electricity transferred by a current of one international ampere in one second.

"As a unit of capacity, the *international farad*, which is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity.

"As a unit of work, the *joule*, which is equal to 10^7 units of work in the C.G.S. system, and which is represented sufficiently well for practical use by the energy expended in one second by an international ampere in an international ohm.

"As a unit of power the *watt*, which is equal to 10^7 units of power in the C.G.S. system, and which is represented sufficiently well for practical use by the work done at the rate of one joule per second.

"As the unit of induction, the *henry*, which is the induction in a circuit when the electromotive force induced in this circuit is one international volt, while the inducing current varies at the rate of one ampere per second."

The Chamber also voted that it was not wise to adopt or recommend a standard of light at the present time. An attempt was made to introduce other units, but the feeling is pretty strong that language-framing electricians must rest on their oars for a time. New ideas and new measurements must have new terms and new names, but the general public must become more accustomed to the new language already invented before proceeding to manufacture more novelties in phraseology. The new terms are even now very difficult to explain, and still more difficult to understand. Moreover, electricians themselves are not sufficiently unanimous either as to the necessity or upon the accuracy of the definitions of

Digitized by Google

the new conditions, and therefore they can afford to wait for a final settlement for a another congress some years hence—perhaps in Paris in 1900.

IV.—The Exhibition.

Nothing grander in design or more beautiful in execution has ever been seen in this world than the group of buildings situated in Jackson Park, Chicago, and called the "World's Fair." It is a great misfortune that the world did not appreciate, nor respond to, the ambitious views of the conveners of this fair. Their conception was magnificent. Their architects, if they did not originate the plans, certainly rose to the occasion. Their builders realised their views. Every possible convenience and accommodation was provided for exhibitors, but the response was poor; and the internal management of the whole business, owing to inexperience and perhaps overweening confidence, was indifferent. The success of the undertaking hovered for some time over failure; but fine weather, patriotism, novelty, real beauty, and cheap fares at last attracted crowds, which, numbering about 200,000 a day, have converted what looked like a disaster into a well-deserved success. I have not much to say of the Exhibition as an exhibition. It was very like its predecessors. It did not attract me; for, having taken part in nearly every exhibition for the last 15 years, I am sick of exhibitions. I devoted much attention to the electricity building, and observed there several novelties, some of which I have referred to in other parts of this report.

Gray's telautograph attracted much attention. It is an improvement on Cowper's writing telegraph. It reproduces the motion of a pen, so that while you are writing in London a phantom hand seems to guide the pen and reproduce your own writing in Nottingham. You can see the pen move, dot the i's, and cross the t's. It makes corrections and erasures. It works well, but very weirdly. My writing and signature were clearly reproduced at the very first trial. But it is immature for practical trial at present. It has not reached its final stage. It is being improved every day. It is very complicated in construction, and it requires four wires to work it. The Western Union Company in Chicago have established a circuit between their head office and stores department, and are giving it a good test.

The French and German Administrations sent admirable and extensive displays of their historical and working apparatus, with a very large staff of men to attend to them; but I am pleased to say that our exhibit proved much more attractive and interesting. It was better arranged and more complete; and our one solitary assistant, Mr. J. Chapman, won golden opinions by the admirable way in which he attended to his duties, and by the excellent verbal explanations he gave of our show.

The United States of America made no historic exhibit; but the Western Union Company showed many relics and examples of Morse's early work. The American public were surprised to find how much we in England had anticipated their work. Morse's first message, "What has God wrought!" was sent only in 1844. Our history commenced in 1837. Our jubilee was celebrated in 1887. Theirs is to be celebrated this year.

An exhibit that attracted much attention was a door which opened before you as you approached it, and closed behind you as you receded from it. This was done by a small electric motor, which was set in motion when you stepped on a mat, and released when you passed through the door. It was worked with the same current that would light a glow lamp. Both on entering the harbour of New York, and on going by steamer from Chicago to the World's Fair, channels for the passage of the steamship were clearly marked out at night by glow lamps fixed on spar buoys, and lighted up in series. There was shown an electric selector of great merit and some originality. It was a plan by which any particular railway station could be selected and called, any particular signal cleared or put to danger, any office on a long circuit with several intermediate instruments selected and secured, any subscriber on a combination telephone circuit—that is, on a single circuit upon which several renters are fixed—could be called and isolated from the rest. All the great manufacturers in the United States made large exhibits of their wares. The American Bell Telephone Company, the Western Electric Manufacturing Company, the General Electric Company, the Westinghouse Company, the Standard Electric Company, had splendid shows but, few novelties. Their novelties have already been referred to, either under electric lighting or electric railways. Electric lifts were on exhibition, and in use. They worked very well indeed, and are rapidly coming into general use in the States. The new Postal Telegraph building in New York is being fitted with several of these lifts, which are going to be worked very quickly indeed (600ft. a minute). They are being installed by the Sprague Company. Electric welding was shown in full operation, and attracted much attention.

Power was transmitted all over the place by currents, and whole exhibits were shown in motion by means of electric motors. Along the machinery hall, 1,400ft. in length, an electric crane, 75ft. span, travelled, and formed an admirable point of observation for those who were allowed to travel on it. It was used in the preparation of the Exhibition to lift and fix all the machinery. It lifts and moves 40 tons. It is worked by five motors. Its weight is 58 tons, and its speed was excellent.

There were large exhibits of every class of cable manufactured in the States—Waring, okonite, kerite, Patterson, dry-core, &c.; and Felten and Guilleaume had in the German section a fine show of their own make. Sections of streets were shown, with pavement, manhole, conduits, joints, and everything complete.

England is the home of the alternator, but it has now taken firm root in America. In 1884 there was not a single one to be found in Philadelphia. Now they are everywhere, and alternate currents are being studied and developed in a way that is completely putting our experimentalists in the back row.

The paucity of real novelties, or of what are commonly known as "Yankee notions," was very marked. The necessity for such things—that is, the scarcity of labour—has apparently disappeared, and with its parent the child has languished. Moore's spark-interrupter—an automatic vibrating armature in a vacuum tube, by which glow lamps can be turned up or down without wasting energy—was described at a meeting of the electrical engineers at New York, but I did not see it at the World's Fair.

The distinguishing feature of the Chicago World's Fair was not alone its uniqueness, but its grandeur and its magnificence. It was not an exhibition of goods and manufactures in the old-world sense. No one seemed to care two straws for the mere trade exhibition *per se*; he admired the beautiful buildings, the waterways, the external attractions, and, above all, the congeries of people that assembled from all quarters of that great continent in such multitudes.

The distinguishing feature of American engineering is the great scale on which it is carried out, and the rapidity of its adoption. An electric railway from Chicago to St. Louis, 250 miles long, is not a difficult engineering feat, for the country is level, but it is novel for the fact that it is projected to travel at the rate of 100 miles an hour.

There were some things in the Exhibition that were extremely interesting. The first was a complete reproduction of an ancient Viking's war-ship—an open boat that would excite fear and trembling even in crossing the Channel, but of a type that probably crossed the Atlantic long before the famous fleet of Columbus. These vessels—the "Santa Maria," "Pinta," and "Nina"—were also reproduced in all their dimensions, and in all their colours and fittings. The contrast between these relics of the past and the modern war-ship built alongside the home of the British Commission, Victoria House, was, to my mind, more suggestive than all the innumerable wares and appliances so freely exposed in the vast extent of covered area.

One interesting building was a kind of baby cloak room, where mothers could book their babies for the day, and who were there carefully tended, nursed, amused, and fed for a very small charge. Each mother received a small brass check, which was her guarantee for the safe custody of her little beauty.

V.—Electric Lighting.

Electric lighting has not generally made the rapid progress during the past nine years in the States that was expected from its great rate of growth during the previous four years. Wild speculation, hasty construction, fatal accidents, and frequent failures have reacted on steady progress. At the same time the advance has been very great, principally in public street lighting. All towns and villages in all parts of the country, however small and isolated, or however distant, seem to have adopted public arc lighting. Arc lamps are found suspended over the roadways in a very rough-and-ready way, sometimes from stretched wires, sometimes from long balanced levers, but always effective. The arc lamp-posts are generally of timber, like telegraph poles; occasionally squared timber, as in Broadway, New York; and sometimes plain and neat iron poles, made of differing sections of iron pipes, but rarely so heavy, massive, artistic, and expensive, as in England. Clear glass globes appear to be almost universal in use. It is quite rare to see frosted glass or opaline shades.

The principal novelty introduced has been the use of flat carbons of oval or elliptic section, to increase the duration of the light. They are 310 millimetres long; the major axis is 25 millimetres, and the minor 11 millimetres. The ordinary arc lamp burns as a rule only eight hours, but this flat carbon doubles its life. Moreover, the flat carbon is found very advantageous and useful with alternating-current systems, on which arc lamps as a rule work badly. The standard current used is 10 amperes, and the energy expended varies from 400 to 500 watts. The lamps burn very steadily as a rule, and give a light of about 800 candles at the angle of maximum intensity.

An excellent self-regulating alternator for public arc lighting, designed by Stanley, was exhibited by the Westinghouse Company. It maintained its current quite constant, however much the number of the lamps was varied, between 0 and 24. Any number could be turned on or off without the least difference being detected in

Digitized by Google

the current or the light. The favourite arc dynamo in the States is said to be that supplied by the Standard Electric Light Company. There was a large exhibit—six machines—of this type in the Exhibition. The largest size worked with 6,550 volts, and maintained 120 arcs in series. It is fitted with a very effective and rapid working automatic governor, regulating the range of the brushes, so that as lamps were turned off the current was maintained constant and the voltage changed. Six seconds only were needed to regulate the brushes from a load of one lamp to fifty lamps. Arc lighting is used very much for shop lighting, not only in the interior for general illumination, but for advertising and attractive purposes outside. Indeed, many of the streets of the principal cities—especially New York and Chicago—are more brilliantly lighted by the shopkeepers than by the municipalities. In fact, in many cities there are many more arcs supplied for private than for public purposes.

Incandescent Lighting.

Glow lamps are, within my observation, invariably used in telegraph offices, post offices, telephone exchange rooms, hotels, and in many railway stations. The electric light is more general in such public places than with us. I did not visit a single place that was not so fitted, and with glow lamps. In private houses it is much used, but not so generally as with us. In Chicago the residential lighting is only 33 per cent. of the total. In all large cities there are immense blocks of buildings fitted with lifts and used as offices, In all cases they were lighted by their own isolated plants. One of the most striking features of a bird's-eye view from some lofty spot of a great city, like New York or Chicago, is the white, fleecy, wool-like jets of vapour that float gracefully away from the top of every large building. They are to be reckoned by the hundred, and every one means steam plant working lifts and electric light. The Western Union Company of New York and Chicago have their own steam plants.

When I visited Chicago in 1884 no central electric lighting station had been built, and no current was supplied. Now, a capital of $2,233,000 earns an income of $320,000 yearly. The glow lamps (16-c.p.) fixed are 136,409, arc lamps fixed 4,376, motors supplied 3,612 H.P., and this is equivalent to 430,000 10-c.p. lamps fixed, or such lamps as we reckon with in England. The maximum load is 50 per cent. of these lamps alight at one time, which accords with our experience in England.

The price works out at 7½d. per kilowatt-hour, or supply unit, and this includes the cost of the renewal of the lamp. The cost of production works out at 3½d. per unit. The cost of the production of electric energy in the States differs, therefore, very little from that experienced here. It is steadily on the decrease. As the load increases, as the daily supply lengthens in duration, as the generators increase in size, so will the cost diminish ; and how low it will fall no one can predicate. Anyway, it will certainly far exceed in economy the production of gas. The price of lamps to the undertaker—that is, to the electric light company—is 1s. 4d. ; the life of the lamp is 600 hours. A 16-c.p. lamp takes 0·45 amperes and 110 volts. It is, therefore, a 50-watt lamp, and a better one than we get at present in England. The screw socket appears to be in universal use. I wish it were so here.

There are three central stations in Chicago. A new station is being built alongside the water in Harrison-street with a capacity for utilising 20,000 H.P., where every modern appliance for cheap fuel, automatic feeding, condensing, and economising will be used. The south side central station is worked by natural gas, which is brought in pipes 100 miles long from Indiana. It is very cheap compared with coal. I found in use in Chicago a system of raising the voltage on the feeders when the pressure falls, owing to the increase of load, by switching in motor-dynamos. They have given the name of "boosters" to these instruments. A somewhat similar system has been applied at the Midland Railway, Derby.

The Exhibition and its surroundings were, of course, brilliantly and entirely lighted by electricity.

The accumulator in America has been a failure for electric lighting, and a very strong prejudice exists against its use. It has led to much litigation, and the best forms seem little known there. The lagoons of the World's Fair grounds were, however, very successfully navigated by extremely pretty electric launches, worked and lighted by accumulators. The grounds at night, brilliantly illuminated and interlaced by winding waterways, with wooded islands and pretty bridges, along which illuminated gondolas and silent launches floated noiselessly, formed most beautiful and fairy-like scenes, superior to anything seen in Venice or pictured by art.

The feature that distinguishes American from English practice is the persistent use of belting and countershafting. In some stations the belting was to English eyes appalling. Direct-driving is only now making its way. There were several direct-driven engines and dynamos exhibited in the American section at the World's Fair, and some new stations now being built are to be direct-driven. The Willans and Robinson engines on show at the Exhibition, and steam turbine exhibited in the Swedish section by Laval—a form somewhat similar to that of the Hon. Charles Parsons, who unfortunately did not exhibit—attracted much attention. The reports of our performances in England are much sought after, and I think one influence of the Chicago gathering will be to convert American engineers to direct driving. The elastic character of direct-driving engines, gradually increasing in number and capacity with the load, and the ability to shut down or turn on engine after engine as the load varies, are economical advantages of immense value. The rapid regulation of small engines, the much smaller space occupied where space is so valuable, the smaller capital expenditure involved, and the reduced working expenses, all give direct driving an advantage which should recommend itself to such eminently practical engineers as the Americans.

The General Electric Company showed in the World's Fair a 1,000 H.P. triple-expansion vertical marine type engine, driving two 400-kilowatt multipolar dynamos, and the Chicago Edison Electric Light Company are fitting up their new central station with direct-driving engines.

The town work at such places as New York, Boston, and Chicago is as solid and substantial as anything we can show in England ; but when we inspect the outlying works in country towns, we can only express our thanks that we have the control of the Board of Trade and the protection of an Act of Parliament. It is the fashion to decry grandmotherly government, and to wince at departmental espionage ; but the protection of life on our railways, the absence of accident in our electric light undertakings, and the character of the work done everywhere, as compared with the same conditions in the States, can lead to but one conclusion, viz., that if we are slower, we do these things at least better in England. It is all very well in the pioneer stage of any industry to let private enterprise have its full swing, but when an industry becomes a public necessity, and when the interests of the whole community are at stake, Government, as the custodians of the public weal, must step in and assume the control. The accidents in the States are terrible in their number and fatality ; and they strike the observant Englishman with dismay. The value of life there seems to be very much below par.

VI.—Electric Railways.

The progress made in the establishment of electric railways is the most wonderful instance of growth of electric industry observable in the States. In 1884 I found only one railway so worked, and that experimentally, at Cleveland. Now every town has its electric railway. There are 4,000 miles of line so worked, 6,900 motor cars, and 4,000 trailing cars.* The capital embarked is $13,000,000, and the rate of progress is scarcely checked by the serious financial depression that has passed over the country. Electrical appliances of all kinds for railway working were among the most conspicuous exhibits at the World's Fair. A special track was laid down for test and trial, and along here I inspected a 30-ton locomotive, the heaviest yet made, having a horizontal pull on the level of 6,000lb., or enough to draw 500 tons on an ordinary English railway. The type of railway in general use over the United States of America is very uniform. We have only one true example in England, and that is at Leeds. A modification of the system has, however, been adopted on the South Staffordshire Tramways, and is about to be introduced in Coventry. The wires are all overhead. A heavy insulated copper wire is suspended over the centre of each pair of rails, or "track," and called the "trolley" wire. This conveys the current from the power-house. It is picked up by a trolley rod, which presses, by the action of a spring, upon this wire, and so conveys the current to the motors, which are geared to each of the two wheel shafts of the car. The current is thence transmitted through the wheels to the rails, and it returns thence to the power-house by heavy copper returns buried in the ground or suspended on the poles.

There are two very fine specimens of electric railways in Chicago. One, the intra-mural railway, conveying visitors to and from different parts of the grounds of the World's Fair, working very well, carrying an immense number of people, and financially very successful. It is not a trolley line, but it has a third rail acting as the main conductor. The other is the Chicago North Shore Street Railway, running to Evanstown. This is a trolley line having iron poles of strong design and good taste. It is 7½ miles long, with a power house situated in the middle of the line. It has 16 motor cars and 16 trailers. The feeders are carried on wooden poles, which are very unsightly. These feeders could have been more economically and more efficiently put underground. In the power house they are using a simple horizontal reciprocating engine, driving a Thomson four-pole dynamo, fitted with carbon brushes, by means of continuous rope gearing. No sparking whatever is observed at the brushes, and nothing can work more smoothly ; but the absence of condensing and the existence of rope gearing

* Trailing cars are not fitted with motors. They carry passengers only, and are drawn by motor cars.

Digitized by Google

must render the engine part uneconomical. The maximum horse-power used is 246. The voltage varies with the load from 500 to 550. The current averages 200 amperes. The maximum number of cars on at one time is nine motors and nine trailers, and this averages at the power-station 13·7 H.P. per car running. The cars run on the straight at from 16 to 20 miles an hour. The rails are 85lb. per yard—a very heavy rail for a tramway. The usual rail is 52lb. per yard, as at Boston; but experience in the United States of America is leading to heavy rails. The pounding and hammering on the rails with heavy loads is very great, and in Philadelphia they are using even 90lb. rails.

The trolley wire alone is not unsightly, but when it is protected with three guard wires, as at Boston, and the same poles carry the feeders, it becomes hideous, and it is astonishing that the American community submit to it. Such a system is impossible in England. This trolley wire must be elastic, otherwise the trolley itself frequently jumps off and stops the car. Attempts have been made to improve the appearance of the road by using handsome central iron poles, with solid brackets on each side to carry the two trolley wires, but the want of elasticity has introduced evils. The trolley frequently comes off, and great sparking is evident.

An admirable illustration of a modern electric railway is the electric *portage* between Lakes Ontario and Erie, from Chippewa to Queenstown, 13 miles long. It is on Canadian soil, and built with Canadian capital, but the work was done by an American firm. It is an open overhead trolley line, with iron posts and brackets. It is worked by water power derived from the Niagara Falls.

The West End railway system of Boston is by far the most extensive electric railway system in any city in the States. In the power station, which is situated on the harbour, there are 24 Babcock Wilcox water tube boilers, each developing 250 H.P. Surface condensing is used, sea water being available for the purpose. There are six horizontal triple expansion engines, each developing 1,000 H.P., and driving by means of belting 18 Thomson-Houston four-pole dynamos, all capable of being connected up in parallel, but put on and off as the load varies. The chimney is 252ft. high and 13ft. 6in. in diameter. It does not smoke, and the steam is generated so economically that only 11½lb. are used for one H.P. hour. There are three power houses in Boston, the other two developing 2,000 H.P. each, so that there are 10,000 H.P. used in Boston for working their street railway system. The line is no longer run by contractors. It is entirely in the hands of the railway company itself. They have magnificent workshops, and a very fine staff. Their chief engineer, Mr. Hirt, was extremely attentive and communicative. He supplied me with capital drawings of the works and general arrangements. The use of belting was again surprising; but I was told that a very large railway system at Brooklyn was going to be worked by direct-driven power, so as to obtain an authoritative and convincing trial of the relative merits of the two systems. I did not learn the type of engine to be fixed at Brooklyn, and I was unable to go there to find out.

The track is light, as I have previously mentioned, but they are welding together the fish-plates and the rails so as to obtain an electrically-perfect return circuit. I saw the car and apparatus used for this welding process; but I could not see it in operation, for one essential part of the plant was being repaired. I saw the electric snow ploughs used to keep the tracks clear in wintry weather. The system of railway working in Boston has given such satisfaction to the public that the traffic returns have improved 30 per cent., owing to the change from horses to electricity. The service is so much quicker, cleaner, and better performed. A railway car in full service is said to run an average distance of 250 miles a day, and its mean speed is 15 miles an hour.

There is an important question under discussion in the United States of America—whether it is better to pursue the present practice of using two motors, one on each wheel axle, or to use only one motor connected electrically and flexibly with the wheels by bevelled gearing. This is the plan advocated and practically carried out by Mr. Sperry. The weight is thus placed in the middle. The horizontal pull is said to be greater. The starting torque is smaller. It is more easily controlled. There is no slip, and the velocity of all parts is uniform. It will climb a stiffer grade. One 35-H.P. motor replaces two 30-H.P. single-reduction Thomson-Houston or Westinghouse motors with economy of energy. The system is working in Pittsburg, where it was adopted after a very severe trial with a Westinghouse car, and it is about to be used on 22nd Street in Chicago. It has this disadvantage—that if the motor fails there is not a second one available to take the car home. The problem is an interesting one, and its solution will be watched with great interest, for it has an important bearing on the economies of our English roads.

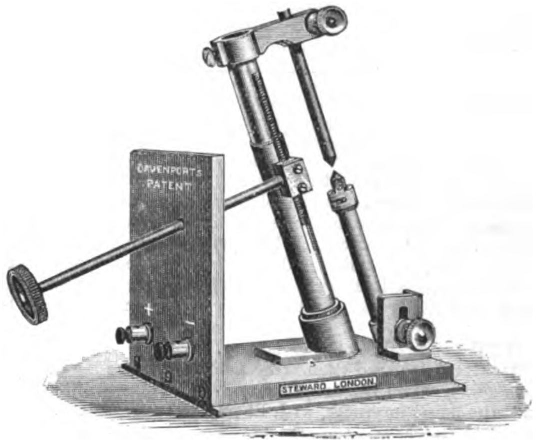
The feeling is pretty prevalent in the States that the conductors must eventually go underground. Experiments in this direction are being made in several directions, notably in Washington and Chicago. The trolley with its guard wires is really an abomination, and the disturbances created by insufficient return accommodation are annoying the telegraph and telephone interests, and alarming the gas and water companies. The future working must be metallic circuits and underground conduits. It is so done in Buda-Pesth, and it has been partially done in Blackpool and in Rome. Other experiments are contemplated in England. No one can doubt that the future of electric railways is very bright. The South London Railway and the Mersey Dock Elevated Railways are examples of great successes in England, but it is in the States, where this form of locomotion has become a necessity, that we are sure to see a speedy and practical solution of the problem.

CONCLUSION.

I have by no means exhausted the notes made during my trip, but I have said enough. Interviewing is a feature of American journalism that, thank goodness, has not taken root here. I was surprised to read of interviews with myself, extending to two or three columns, that resulted from the passage of a few compliments; but I was more surprised to find that statements supposed to have been made by me to an interviewer were taken *au sérieux*. One irate functionary compared an official statement of our Postmaster-General with a mythical statement made by me, and triumphantly pointed out such a glaring contradiction as a complete refutation of my fallacies. I even read that I had stated that we electricians in England had *nothing* to learn from America. I have no recollection of ever having made any remark which could by any shorthand blundering have been construed into such an absurdity; but if I had done so it would more likely have been one where "nothing" was a telegraphic error for "everything." I cannot too gratefully speak of the attention and kindness I received from everyone, and I certainly feel that I have personally profited from my visit very much indeed. A visit to the United States is something like charging an accumulator. It stores the visitor with energy. When I am discharged, and my adverse criticisms have been forgotten, I shall probably cross the Atlantic again.

THE DAVENPORT ARC LAMP FOR OPTICAL LANTERNS.

The accompanying illustration shows a remarkably simple form of arc lamp which has recently been designed by Mr. G. Davenport for use in the optical lantern, and for projection purposes generally.



The lamp consists of two carbon holders, so arranged that, while the lower carbon is automatically maintained in the proper position for burning by a spring within the lower carbon tube, the upper carbon is fed forward, from time, to time as the carbon is consumed, by a rod at the back of the lamp attached to a rack-and-pinion arrangement. It will burn about five minutes without attention. The tube containing the lower carbon is fastened by a thumbscrew to a fixed upright plate, having a slot cut in it so that the height of the tube may be varied and other adjustments made. The two carbons are set at an angle so that the full benefit of the arc is obtained directly in front.

The lamp is made of such size and shape that it will fit any ordinary lantern without alteration, thus allowing of the limelight or other luminant being used when the electric current is not available. The rod carrying the pinion for feeding the upper carbon projects at the back of the lantern, and the only attention necessary in using the lamp is to turn this rod from time to time in a similar manner to that required when turning the lime for the limelight.

The lamp works with from six to eight amperes, and requires an E.M.F. of not less than 60 volts. Carbons 8 m.m. in diameter

should be employed, and the lower carbon should be adjusted so that its point is slightly in front of the point of the upper carbon, and the upper carbon, when burning, should be kept at such a distance that the point of the lower carbon is nearly clear of the crater formed on the upper carbon by the arc. It is found that the normal length of carbon fitted to the lamp lasts two hours, with a little carbon to spare.

The source of light being of small area enables splendid definition to be obtained. The risk of damage to slides from the heat of the arc light depends principally on the amount of current consumed in the arc. With a lamp giving a light two or three times greater than that given by the best mixed jet, the heat is not sufficient to injure any ordinary gelatine slide, and the risk from this source is much less in proportion to the light obtained than with any other form of artificial light.

The Davenport lamp is made by Mr. J. H. Steward.

LEGAL INTELLIGENCE.

Gold Trust and Investment Company (Limited) v. Electric Tramcar (Limited).

This was a motion in a debenture-holder's action to commit Alfred James Jarman, of 71, St. John's-hill, Clapham Junction, and Watson Smith, of 63 and 64, New Broad-street, to prison for contempt of Court in interfering with the Receiver of the Court by having taken away from a certain shed accumulators and other property of the defendant Company, and was heard in the Chancery Division, on Friday, before Mr. Justice North. It appeared that Jarman was a person who had been employed by the Receiver, and had a key of the shed. Watson Smith was manager of a company called the Elieson Accumulator Syndicate. He had contracted to buy from the Receiver certain tramcars, accumulators, and plant for £250, and patent rights for £10, to be paid on delivery. He purported to sell the same chattels to the Elieson Accumulator Syndicate for £2,000, partly to be paid for in debentures. That Company immediately contracted to sell the same property to a trustee for a new company for £15,000. The accumulators and some other goods were removed by Watson Smith, with the aid of Jarman, without paying anything or leave from the Receiver.

Mr. J. W. CLARK, for Jarman, pleaded that the conduct of his client was *bonâ fide*, though mistaken.—Mr. Watson Smith appeared in person.

Mr. JUSTICE NORTH made an order for the committal of both Jarman and Watson Smith. In the course of his judgment he observed on the difference of amount between the prices named in the three contracts. He could not say whether the price in one case was too high, or in another too low. That he had nothing to do with. Commenting on the evidence, he said he could not see anything *bonâ fide* in the conduct of the respondents; on the contrary, he might give it a very different name. As an order for committal was pressed for, he must make it.

Hammond v. Brighton and Hove Electric Light Company (Limited).

This was a debenture holder's action, which came before Mr. Justice North on Saturday, upon agreed minutes.

Mr. EVE, who appeared for the plaintiff, stated that debentures were issued to the amount of £15,000, each of the value of £100, bearing interest at the rate of 6 per cent. The principal moneys were repayable on January 1, 1895, or earlier if default was made in payment of the interest. The Company had made default in payment of the half-year's interest due in January last, and a receiver and manager had been appointed.

Mr. CHITTY appeared for the Company.

His LORDSHIP declared that the holders of the Debentures were entitled to a charge upon the property and undertaking of the Company, and directed the usual inquiries, with liberty to apply, as to a sale.

Tibbits v "The Morning."

This case, which was similar to others in which the plaintiff (well known in recent "electropathic" belt actions) has appeared, was heard on Friday and Saturday before Mr. Justice Lawrance and a common jury, and resulted in a verdict for the defendants. It was an action for libel, in which the plaintiff claimed heavy damages.

Edison-Bell Phonograph Corporation (Limited) v. Smith and another.

In this action, the hearing of which was resumed on Saturday last, Mr. Justice Wright, on hearing the arguments of council upon both sides, gave judgment for the plaintiffs with costs, and granted a certificate of the validity of the patent, and an injunction against the defendants. His reasons for this judgment, and the summing up the whole case, was deferred.

Paper as an Insulator.—Prof. Elihu Thomson is making use of an insulator consisting of sheets of paper impregnated with a mixture of kaolin and silicate of soda.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 27, 1894.

The Rowland Suit.—The decision of the Federal Court, awarding Prof. Rowland $9,000 in his suit against the Cataract Construction Company for services rendered in connection with the Niagara electric plant, is much less than the amount claimed—$30,000—but as Prof. Rowland originally only valued his services at $10,000, in a bill rendered, the verdict is really a favourable one to him. A feature of the case was the evidence produced showing a most bitter feeling toward Prof. Forbes on the part of Prof. Rowland, which was further illustrated by the testimony of Prof. Rowland in the witness box. The verdict merely recognises the value of Prof. Rowland's services aside from any question of priority, and in fact, none of the testimony established that he had originated a single feature of the Niagara plans; on the contrary, the testimony of one of the principal officers of the Construction Company, of Prof. Forbes, and documentary evidence offered were distinctly against this claim, and moreover decidedly favourable toward Prof. Forbes.

An Edison Lamp-Patent Decision.—A Judge of a Federal Circuit, on January 23rd, dissolved an injunction against a lamp manufacturer at Cleveland, O., who had been and declared an infringer of the Edison lamp, on the ground that the American Edison lamp patent had expired with the English patent, on November 10, 1893. It was claimed that the endorsement of that date by the Edison attorney on the American patents was analogous to an election of remedies, and accordingly cannot now be shifted, which view was sustained by the Court. All other Courts have heretofore held that the date of sealing the English patent is the one to apply in determining the effect of the expiration of a foreign patent on an American one, and that the mistake of the Edison attorney in endorsing the wrong date had no effect in law.

The $50,000 Electric Traction Prize.—It is said that more than 200 different street railway conduit systems have been submitted to the Metropolitan Traction Company of New York in competition for the $50,000 prize offered by it. As the time expires in March, however, and a successful system must demonstrate the required qualities under actual working conditions, it does not seem that any inventor will be able to even prepare to compete under the conditions in this limited time.

CORRESPONDENCE.

DOUBLE-ACTING GAS ENGINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of December 22nd an article appeared upon the driving of alternators by gas engines by Mr. J. Emerson Dowson, in which reference is made to double-acting gas engines. The author's expression of opinion is so severely unfavourable to the double-acting gas engine that, unless challenged, it may do serious injury to the reputation of this class of gas engine, and especially so with some readers, who are apt to accept for fact what they see in print, regardless of whether the author knows anything about his subject or not. As Works Manager for Messrs. Dick, Kerr and Co., of Kilmarnock, who are the only makers of double-acting gas engines, and who are also makers of single-acting gas engines, I would ask you to permit me to say a few words in endeavouring to show that the double-acting gas engine is too good an engine to be "damned with faint praise" by being called merely "ingenious," and then with a waive of the hand to be consigned to oblivion in the words: "We need only consider the well-known single-acting engines," &c.

Mr. Dowson says:—"With the double-acting engine, however, more oil and more water must be used to prevent the over-heating of the pistons, and there are twice the number of gas, air and exhaust valves, as well as twice the number of ignition tubes to be kept in order, compared with those of single-acting engines."

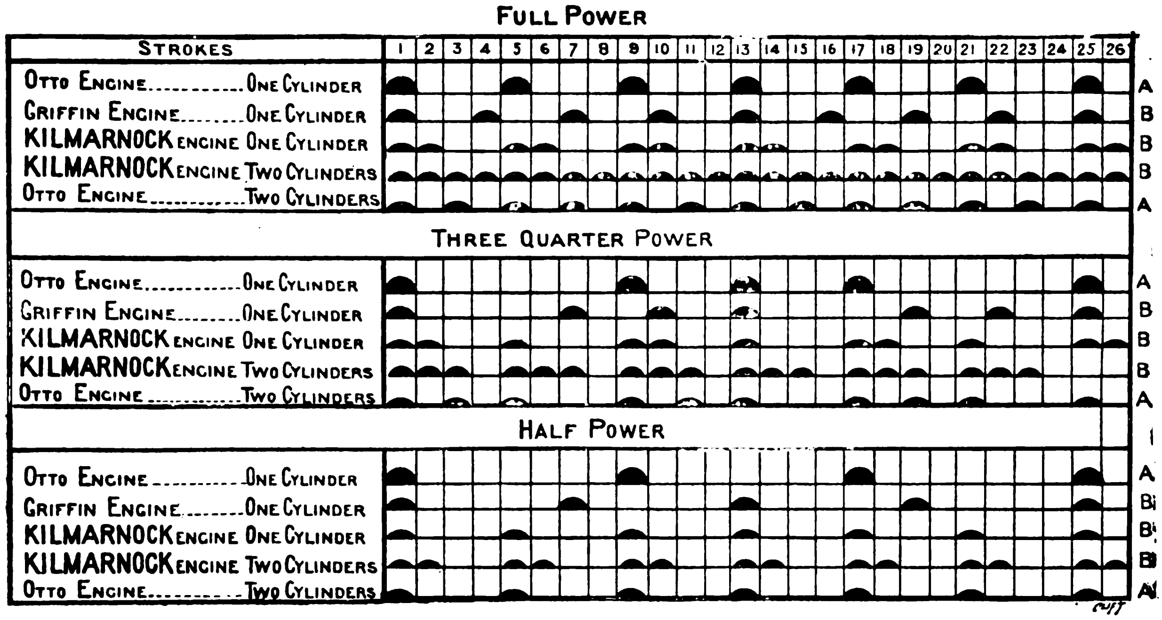
Digitized by Google

It is true that in double-acting engines two admission valves, two exhaust valves, and two ignition valves are required, but only one gas valve. The works of Messrs. Dick, Kerr and Co., have during the last seven years turned out hundreds of double-acting gas engines, and hitherto only three or four valves have required renewal, but not so with cams, and the valves instanced have been damaged through accident or neglect. This being the case, and the valves in question for equal power engines smaller than in single-acting engines, the greater number of valves cannot be of serious moment.

Mr. Dowson states that more oil is used; this statement requires proof. My experience with both classes of engines shows that there is little or no difference in this respect, and as the circulation water is used over and over again, I quite fail to see the loss from this source. The gas engine originally made by Messrs. Dick, Kerr and Co., was known by the name of the "Griffin Gas Engine." This was a six-stroke cycle engine having a scavenging stroke. This engine gave very fair results, but was found to be not quite so economical in working as the Otto Cycle Gas Engine, and hence, acting upon the writer's suggestion, a double-acting Otto Cycle Gas Engine was constructed, the results being of an extremely satisfactory nature. The manufacture of these engines was at once commenced, and the engines so constructed are behaving area only of the single-acting engines, less trouble is likely to arise from this source, and engines of larger sizes are thus possible on this system.

Our double-acting gas engines when driven with carbon monoxide, frequently known as "Dowson Gas," can be started in a very simple manner from the small boiler which supplies steam to the generator, and as larged-sized gas engines and engines for electric lighting are now being made a speciality by Messrs. Dick, Kerr and Co., this mode of starting is especially convenient. A steam pipe is led to the back end of the cylinder, and the largest gas engine can be started at a moment's notice as readily and easily as a steam engine. For electric lighting, where extra steadiness is required, and also in cases where higher powers are asked, the practice of the principal firm of gas-engine makers is to apply two single-acting gas engines having the connecting rods coupled to the same crank. This device answers the purpose of, and gives the same cyclical result, as one of our double-acting gas engines; but it entails two pistons and two connecting rods, and these would surely use more oil than one piston, &c., and would have more parts and would be less under control than one of our double-acting gas engines, and yet Mr. Dowson says, "We need only consider the single-acting engines." We are now constructing gas engines with two

COMPARATIVE CYCLES OF GAS ENGINES



admirably, and leave nothing to be desired in their steadiness of working and economy and in the fact that they are especially suitable for large powers.

An engineer who would advise that a large Corliss valve steam engine should be made single acting because it would require valves at one end of the cylinder only, and would save complication, oil, &c., would be regarded with curiosity, to say the least of it, and this is practically what Mr. Dowson says. I maintain, however, that if a steam engine should be made double-acting there is the same necessity in a gas engine, even in a greater degree, for the following reason, amongst others:

The advantages of double-acting gas engines over the single are, first, greater steadiness, as illustrated by the cycle diagram annexed, reduced violence of explosion impulses, these being only half the force, the shorter intervals between the explosions, lighter flywheels, reduced weight, crank shaft, &c., and less costly foundations, and especially in the greater ease of starting, and on light loads giving half-power cut-outs with, therefore, greater steadiness than with single-acting gas engines.

It is well known, in dealing with large powers, that heat is more difficult to control in large cylinders than in small ones, and more trouble exists from the excessive heating and expansion of the piston, and it is obvious that in engines of equal power, the piston of the double-acting engines being half the cylinders, each being double-acting and having nearly four times the number of parts of a single-acting engine. We have now under construction at Kilmarnock four such gas engines, each 100 H.P. These engines will have two double-acting cylinders and have two impulses to each revolution, or 320 impulses per minute, and this type of engine has been adopted by the Belfast Corporation, under the advice of Prof. Kennedy, for the central electric lighting station at Belfast.

Apologising for trespassing to so great an extent upon your space.—Yours, &c., J. W. HARTLEY,
Britannia Engineering Works, Kilmarnock.

Kilmarnock, January 31, 1894.

ALTERNATING v. CONTINUOUS CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The opening remarks of this week's leader, which says—"The rivalry between alternate currents and continuous will not cease for many a year: and it is commonly supposed that it will only be diminished when experience has proved that, other things being equal, districts exceeding a certain size should take advantage of the economies of the former, while smaller areas may enjoy the conveniences of the latter"—has an amusing but instructive confirmation in in your advertisement pages. On page 25, the Brush

Digitized by Google

Company, *the leading advocates of the alternating high-tension system* (in italics please) advertise a representative continuous-current bar armature machine, which forms one of a series I have designed for that Company, and which is similar to two machines of 100 and 144 kilowatts output just being supplied to the Lancaster Corporation; and on the other side, page 26, there is an illustration of an alternator designed by Mr. Brunton for Messrs. Crompton and Co., who have for years so persistently advocated low-tension continuous currents, but who are now, apparently, making strenuous endeavours—*vide* Newport tenders—to get a foothold in alternate-current work.

Who can wonder that some of the younger members of the profession will begin to doubt some of the cocksure statements of much-respected elders, and ask in a slang, but expressive, phrase, "Where are we now?"—Yours, &c.,

ERNEST SCOTT, A.I.E.E.

Falcon Works, Loughborough, Leicestershire, February 2, 1894.

MINIMISING HEAT LOSSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The method of minimising loss of heat from electrically-heated vessels, referred to in your "Notes," as proposed by Mr. Fessenden, is not new, as you remark. I have experimented with this method and employed it for some time. I have shown two electrical ovens at the Cookery Exhibition at the Portman Rooms in the month of November last. One of these ovens was made of two jackets of bright tin with air space between them of about half-an-inch, the other being made of bright brass with an inner and outer jacket kept as bright as possible.

I have, however, found that in practical use difficulties are encountered which negative to a large extent the favourable results obtained by laboratory experiments. There may be uses for electrically-heated chambers in which the inner surface can be kept comparatively bright, but in practical cooking this cannot be obtained, and very soon after the operation of cooking begins the very great efficiency of the reflecting bright surface is lost. Another difficulty is, that it is not always possible to make an inner and outer jacket in such a manner that they do not touch and offer heat conducting surfaces between themselves. They may touch between themselves at the bottom, but to obtain a good efficiency it is most necessary that the top half should constitute an uninterrupted latent air chamber. There is no doubt that in electrically-heated ovens bright and smooth surfaces will have to be used whenever possible, as the loss by radiation from black surfaces, such as are now used with ordinary gas ovens, is so great as to make the oven practically useless owing to the large current required to maintain the heat.

Out of the great many experiments I have made upon this subject I will select the following:—

Oven, outside bright polished brass, and inside enamel. Time. 10min.; power, 950 watts. Result: Temperature raised from 60 to 330°F.

Same oven, outside blackened, and inside ordinary sheet iron. Time, 10min.; power, 970 watts. Result, temperature raised from 59 to 165°F.—Yours, &c., G. BINSWANGER.

69 and 71, Queen Victoria-street, London, E.C., February 6, 1894.

MESSRS. NALDER BROS. AND CO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Owing to the numerous inquiries we have had recently as to whether we have changed the constitution and address of our firm, we feel it incumbent on us to state that there has been no change whatever, and that the partners, F. H. Nalder, H. Nalder, C. W. S. Crawley, and A. Soames, who have conducted the business during the last six years, still carry it on as Nalder Bros. and Co., and that our sole place of business is at 16, Red Lion-street, Clerkenwell, London, E.C., as heretofore.—Yours, &c., NALDER BROS. AND CO.

London, E.C., February 6, 1894.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1894 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

Copies are being despatched in the order of subscription, and the Publisher hopes to be able to forward by Tuesday next all the books ordered.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

TENDERS INVITED.—The Northern Co-operative Company invite tenders for supplying and fitting up electric wiring and fittings at their central stores at Aberdeen. Mr. J. Ferries, 54, Loch-street, Aberdeen, is secretary, and tenders must be in by the 20th inst.

——— The Guardians of Dewsbury Union invite tenders for lighting the workhouse and premises by electricity. Tenders must be sent in to Mr. J. Peace, Clerk to the Guardians, by Thursday, the 15th inst.

——— The South Indian Railway Company (Limited) requires tenders for the supply of general stores, including telegraph stores and sundries. Particulars may be obtained at the Company's offices, 55, Gracechurch-street, E.C., where tenders must be sent not later than noon on Tuesday next.

TENDERS ACCEPTED.—The Lord Provost's Committee of the Edinburgh Town Council have accepted the following estimates in connection with the electric lighting station in Torphichen-street, the tenders in all amounting to £24,300:—

George Sinclair, Leith—boilers, &c.	£6,024
Siemens Brothers and Co. (Limited), London and Woolwich—engines, dynamos, pipes, pumps, &c.	15,098
Siemens Brothers and Co. (Limited)—switchboard connections, &c.	1,760
Crompton-Howell Electrical Storage Company (Limited), London and Llanelly—storage batteries	1,400

——— The Halifax Corporation have accepted various tenders in connection with their new central lighting station in Foundry-street, at a total cost of between £8,000 and £9,000.

——— The Highways Committee of the Sunderland Town Council have accepted tenders for the erection of buildings required at the electric lighting station, chimney shaft, and iron roofing, which were estimated to cost about £3,015. The lowest tender received was for £3,167, and has been accepted. The tender of Messrs. J. Abbott and Co., of Gateshead, has been accepted for the iron roofing at £235.

——— The Electric Lighting Committee of the Belfast Corporation have accepted the following tenders:—For tandem and single engines (to work with Siemens' dynamos), Messrs. Dick, Kerr and Co. (Limited); switchboard, Messrs. J. H. Holmes and Co.; batteries, Electrical Power Storage Company (Limited); road work, Messrs. Scott and Seller; cast iron work, Messrs. Maclaren and Co.; insulators, Messrs. Doulton and Co.; vulcanised bitumen, the Callender Company; leads, the British Insulated Wire Company (Limited); copper strip, Messrs. Curtis and Sons—the whole of the tenders amounting to £12,984.

——— The Coleraine Guardians have accepted the tender of Mr. J. McCandless for the supplying and fitting up of thirteen electric bells and indicators at the Workhouse Infirmary for £7. 9s. 6d.

APPOINTMENT VACANT.—The Blackpool Corporation require for their tramways a resident working electrical engineer. Particulars of the appointment will be found in our advertisement columns, and applications must be sent in before the 19th inst.

——— The Corporation of Edinburgh require a resident engineer for their central electric light station. Candidates must have had a thorough training both as mechanical and electrical engineers, and have had practical experience in central station working. Applications must reach Mr. William Skinner, the town clerk, on or before the 24th inst. Further particulars appear in our advertisement columns.

Digitized by Google

LIQUIDATION.—At meetings held on December 18th and January 15th, it was resolved by the shareholders of Easton and Anderson (Limited), to voluntarily wind up the Company, and to reconstruct under the title of Easton, Anderson and Goolden (Limited), Mr. T. P. Wilson, of 3, Whitehall-place, S.W., being appointed liquidator. Particulars of the formation of the new Company appeared in our last issue.

BANKRUPTCY DIVIDEND.—In the matter of Frederick Silvester, trading as F. Silvester and Co., at Newcastle-under-Lyme, a first and final dividend of 4s. 6½d. in the £1 has been declared by Mr. C. E. Bullock, the trustee, of 15, Albion-street, Hanley.

ENGLISH-MADE CARBONS.—In reference to the question of carbon rods and plates being made in England, the Atlas Carbon Manufacturing Company (Limited) desire us to notify that they have for some years made both lighting rods and battery plates at their London works.

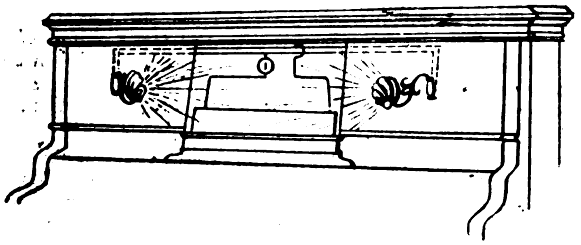
MESSRS. NALDER BROS. AND CO.—We have received a copy of the latest catalogue issued by this well-known firm of electrical and scientific instrument makers. The list contains illustrations of a number of new instruments and apparatus, and we may specially mention that the firm are now supplying the Ewing magnetic curve-tracer in a convenient form for testing purposes, besides a number of other instruments for similar work. New apparatus for central stations and electrical engineering work are also shown, in addition to the instruments, &c., used in teaching and other laboratories.

ELECTRIC FIRE ALARMS.—An advertisement supplement issued with our current number gives illustrated particulars of the system of fire alarms in use by the Fire Brigade Department of the London County Council. About 600 of these posts are erected in the metropolis, and we learn that considerable orders have been dealt with by the Single Wire Multiple Telephone Signal Company, of 50, Old Broad-street, London, E.C., who own the patents.

GAS LIGHT AND COKE COMPANY.—This Company is straining every nerve to make up for any possible diminution of receipts owing to the steady increase in the numbers of those using the electric light in the City of London district. The Company's latest departure is the issue of a budget of pamphlets setting out the advantages of gas as a cooking and heating agent, and we have to acknowledge the receipt of a variety of pamphlets and circulars showing the Company's charges for rentals for stoves and for domestic heating and cooking apparatus, a departure which manufacturers of electric cooking and heating plant and apparatus might well follow. The average city man requires certain light and quickly-cooked food during business hours, and as soon as he can obtain electric current is likely to become a customer for the simple and easily-managed apparatus, which certain electrical firms are placing before the public, but it is essential that he should know what he can obtain, and where.

GAS ENGINES.—A patent duplex high-speed gas engine will be on show running next week in the show rooms of the Indestructible Gas Ignition Tube Company (Limited), 100c, Queen Victoria-street, E.C.

ELECTRIC LIGHT FOR THE PIANO.—At Anderton's Hotel, Fleet-street, London, on Monday last, Messrs. A. Allison and Co., of Apollo Works, Leighton-road, London, N.W., pianoforte builders, had on view one of their most modern instruments effectively lighted by electricity. The sketch herewith shows the position of



the lamp, and it will be seen that under the music board a space is provided sufficient to contain a portable battery, a switch, and the necessary electrical connections for lighting two incandescent lamps. This is effected by making the music board slope at a more pronounced angle than usual, but does not otherwise interfere with the usual arrangements. The whole of the front can be lifted out, including the battery and lamps, leaving the interior free for tuning as usual. The arrangement is ingenious, and is the invention of Mr. Allan Fraser. A lithanode battery is used, which, when in position, is securely fastened with lock and key, and there is no communication between the electrical apparatus and the interior of the instrument. The battery can be easily lifted out for re-charging.

ALLEGED THEFT OF DESIGNS.—Henry H. P. von Weber, of Moore Park-road, Fulham, was charged at Westminster on Monday with stealing eleven designs of electric light fittings (valued at £8), the property of Mr. H. Foote, of Messrs. Statter and Co., Westminster. It appears that the Company advertised for a draughtsman, and that amongst the replies was one from the prisoner (who had been in the service of the firm), submitting designs which were marked with the firm's stamp, and were the firm's property. Upon presenting himself, in answer to his application, he was given in charge of the police. Evidence was adduced which clearly proved that the designs were stolen, and the prosecutors complained of the difficulty they had in preventing their designs passing into the hands of pirating firms. Mr. Foote explained that he had promised the prisoner's father not to press the charge against his son, and this being the case, Mr. de Rutzen, the magistrate, allowed the prisoner to be discharged, cautioning him against similar conduct in future, and pointed out that it was entirely owing to Mr. Foote's generosity that he obtained his discharge.

ALLEGED THEFT.—Two men, named Bonette and Denny, were charged at West Ham, on Wednesday, with stealing 420 yards of telegraph wire, the property of the Postmaster-General. The wires connected the West Ham Fire Brigade with various street fire-alarms and factories in Stratford, and during the past month the connections have been cut on several occasions, and lengths of wire stolen. On Monday night the bells in the Stratford Fire Station began ringing, and as the connection was found broken it was concluded that the ringing was caused by the end of a wire being in contact with earth. Communication was made with the police-station, and at once a large number of police officers were sent out to scour the neighbourhood where the wires were placed. Constables went on to the sewer embankment, on the High-street, Stratford, and met the prisoners carrying the roll of wire.—A remand was granted.

"ENGINEERING MAGAZINE."—The February number of this magazine contains the usual amount of interesting and instructive reading. The contents include "How the Ancients Moved Heavy Masses," by W. F. Durfee; "Labour's Delusion Regarding Capital," by Alfred H. Peters; "Industrial Conditions in Mexico," by John Birkinbine; "Small Electric Light Stations," by J. E. Talbot; "Electricity in Suburban Development, from the Business Man's Point of View," by Erastus Wiman; "The Joplin Zinc-Mining District," by Hamilton S. Wicks, &c. Most of the articles are illustrated in the manner which has made this magazine so universally popular. Subscriptions for the European edition, 12s. 6d. per annum, should be sent to Mr. George Tucker, Salisbury-court, Fleet-street, E.C.; single copies are 1s. each, or 1s. 3d., post free.

TELEPHONE SUBSCRIBERS.—The National Telephone Company have just issued to their subscribers a supplementary list, dated January, 1894, and consisting of 55 pages of additions and corrections to the latest previously-issued list.

MESSRS. FARADAY AND SON'S CANDLE FITTING.—We omitted to mention in our notice of this fitting last week that the arrangement is patented.

ANNUAL DINNER.—The third annual gathering of the staff of the New Telephone Company (Limited), Manchester, took place on Friday evening last, at which a party of upwards of eighty ladies and gentlemen participated.

ABERDEEN.—The Watching and Lighting Committee of the Town Council have suggested, in connection with the public lighting, and as an experiment, that iron brackets should be attached to two or three of the electric lighting pillars between Castle-street and Market street, and that incandescent lamps should be placed on these brackets and lighted after the arc lamps are extinguished at midnight. The suggestion has been adopted.

BASINGSTOKE.—Inquiries were made at the last meeting of the Urban Sanitary Authority as to the steps being taken to introduce the electric light into the district. The Chairman of the Board stated that little or no progress had been made in the matter, as it was advisable to wait a further development of electric-lighting systems before proceeding. Several members of the Board are about to visit Fareham to inspect the lighting of that town.

BEDFORD.—In reference to the proposed transfer of the Bedford Provisional Order to the Bedford Electric Light Company (Limited), which the Board of Trade has disapproved, it appears that the Local Authority made fourteen objections to the transfer.

BIRKENHEAD.—The sub-committee recently appointed to advise the Finance Committee as to the steps to be taken in regard to the carrying out of the provisions of the Birkenhead Provisional Order, 1890, have sent in their report. They recommend an electrical engineer should be appointed to advise the Corporation as to the details of the system of lighting to be introduced, and have advised the appointment of Mr. J. N. Shoolbred, of London. The Finance Committee have confirmed this appointment, and the sub-committee are considering, with Mr. Shoolbred, the question of site, plant, &c.

Digitized by Google

CHELMSFORD.—A special meeting of the Town Council was held on Tuesday last to discuss portions of the Provisional Electric Lighting Order applied for by Messrs. Crompton and Co., and the Council accepted clauses giving them power to purchase by arbitration at the end of 21 or 31 years. It was necessary before agreeing to the above clauses to rescind a resolution previously arrived at by the Council.

CLUB LIGHTING.—The new Constitutional Club at Leicester is to be partly lighted by electricity, and Messrs. Matts and Biggs are fixing combined gas and electric light fittings throughout the building.

——— The Nimrod Club, devoted to the special interests of hunting men, has recently taken the premises lately occupied by the Salisbury Club in St. James's-square, London, the premises having been renovated and redecorated, and the new fittings and apartments of which have been brought quite up to date. The rooms have been handsomely fitted throughout for the electric light, and this particularly refers to the billiard-room, which is one of the finest in London. The Nimrod Club is having extensive new club premises built upon the site of Cleveland House, which will be completed in about two years, and which is to be fitted throughout for the electric light.

COLCHESTER.—Mr. W. H. Massey has advised the Lighting Committee of the Town Council that, as the electric lighting works under the Colchester Provisional Order would probably be carried on in conjunction with other undertakings of the Corporation, and as money could be borrowed by the Corporation at a low rate of interest, the Council will be able to supply electricity and make the undertaking a remunerative one. Mr. Massey has been instructed to prepare a further report.

COVENTRY.—Messrs. G. and I. Steane have been appointed architects by the City Council for their electric lighting station, and tenders for the building are to be invited forthwith.

DOVER.—The Town Council recently appointed an expert to report to them upon the electric lighting arrangements, and Mr. W. Slingo's report was before the last meeting. Mr. Slingo points out several matters that require the attention of the Corporation officials. A copy of the report has been sent to the Board of Trade. It is probable that the Electric Lighting Committee of the Town Council will be reappointed.

——— The staff of the local gas company have recently held a concert, at which the manager pointed out that now the company were in active competition with the electric lighting company, it was necessary that unity should prevail among the Directors and the employes.

DUBLIN.—The Corporation's gas lighting arrangements cause that body considerable trouble, and a lengthy discussion took place at the last meeting, which ultimately led to a resolution being proposed for the amalgamation of the Gas and Electric Lighting Committees into one body. It is proposed that the Committee should be formed of the members now constituting the Electric Light Committee and one member from each ward not now represented on that body, the Committee to have all the duties and powers of the Paving and Lighting Committee, the Electric Light Committee, and the Special Gas Committee. The final decision will probably be come to at the next meeting of the Corporation.

DUNDEE.—A deputation of the Glasgow Town Council, including Mr. P. Burt (Chairman of the Lighting Committee) and Mr. Arnot (the electrical engineer), visited Dundee last week to inspect the condensing plant which has recently been supplied by Messrs. Whyte and Cooper to the electric lighting station, the visitors being highly pleased with the results obtained. It is announced that the Dundee Commissioners are sanguine that the revenue from electric lighting will more than fulfil their expectations, and the whole scheme is voted a great success.

HOWTH.—Application is about to be made, under the Irish Tramways Act, for power to lay an electric railway from Dublin to the top of the Hill of Howth. The proposed line is to start from the terminus of the Dublin tramways at Dollymount, and is to proceed along the present level road by the seashore. Electricity is to be used as the motive power throughout the line, and when this is completed it is suggested that the Dublin Tramways Company should obtain powers to run electric cars on their line, from Nelson's Pillar to Dollymount. The engineer to the scheme is Mr. F. G. Fraser, C.E.

KENSINGTON (LONDON).—At their last meeting the Vestry received a lengthy report on the electric lighting question from Mr. Philip Monson, and after considerable discussion referred the report to the Select Electric Lighting Committee for digestion.

LEICESTER.—It will be remembered that considerable discussion has arisen at the Corporation meetings concerning the tenders for the supply and erection of engines for the town electric lighting scheme, and at a meeting last week Mr. Alderman Lennard moved that (in conformity with the report received from the engineer and manager of the Corporation Gas Department, Mr. Alfred Colson, M.I.C.E.) Messrs. Hick, Hargreaves and Co.'s tender for the sum of £4,695 be accepted. He said that complaint had been made that the committee who had the matter in hand had so drafted the specification for the engines that little originality was left to contracting engineers in designs for the work; but he protested that this was not the case, and that, although several firms had written declining to compete owing to the severity of the conditions of the specification, this was chiefly owing to the fact that these firms had little or no experience in the supply of engines for electric lighting work. After going carefully through the tenders sent in, the Corporation Engineer could only recommend two designs, namely, those of Messrs. Musgrove and Co. and Messrs. Hick, Hargreaves and Co. The former tender was £1,000 in excess of the latter, hence the proposal to accept the latter tender. The tender of the local firm of engineers, Messrs. Jessop and Co., regarding which so much feeling had been shown by the members, was not recommended by the engineer, although he (Alderman Lennard), as Chairman of the Committee, was struck with the excellence of design of the engines tendered for by that firm. It appeared, further, that Messrs. Hick, Hargreaves and Co. provided 10 H.P. in excess of that provided by Messrs. Jessop and Co. Alderman Lennard entered into an exhaustive justification of the action taken by the Committee. An amendment was moved that Messrs. Jessop's tender be accepted, but ultimately, after a long debate, the Committee's recommendation, that the tender of Messrs. Hick, Hargreaves and Co. be accepted, was carried by 36 to 15.

MANCHESTER.—At the last meeting of the City Council the Parliamentary sub-committee's report was presented, dealing chiefly with the subject of arrangements to be made with the National Telephone Company, and to decide whether the wires were to be allowed to be continued overhead. The sub-committee ultimately decided to recommend that they be authorised to enter into direct communication with the National Company in regard to the laying down of underground wires within the city, and to report subsequently to the Council.

MONMOUTH.—At the monthly meeting of the Corporation on Monday correspondence was read from the Local Board, in which the latter body declined to grant borrowing powers for electric lighting until a Provisional Order has been obtained; and the Board further question the practicability of using the water from the River Wye as motive power. It was ultimately decided to engage Messrs. Bramwell and Harris to examine and report on the practicability or otherwise of the turbines for the proposed lighting, and upon receipt of their report to again approach the Local Government Board on the subject.

MUSEUM LIGHTING.—The annual inspection of the Kelvin Grove Museum and the Glasgow Corporation Galleries of Art were made last week by the sub-committee of the Town Council appointed for that purpose. Throughout the handsome buildings the electric light has been installed to the satisfaction of the Committee and of everyone concerned. The apparatus includes 50 Crompton arcs.

RUTHIN.—The Town Clerk has been directed to call a meeting of the Electric Lighting Committee, and to prepare and present a report to that body on the subject of the electric lighting of the district.

SCARBOROUGH.—The Corporation have decided to light the Town Hall by electricity.

STAFFORD.—The Local Government Board have sanctioned the borrowing by the Town Council of £20,000 for Electric Lighting purposes. Offers have been made to the Gas Committee for the purchase of certain lands for the use of the Electric Lighting Committee, which body have reported to the Council on the subject of obtaining tenders for buildings and machinery. The Committee's report has been adopted.

STRAND (LONDON) BOARD OF WORKS.—A remarkable report has been presented by Mr. A. Ventris, surveyor, on the public lighting of this important district. He states that he has made a careful survey of the streets and courts of the neighbourhood, and is of opinion that the lighting power of the public lamps compares unfavourably with those of the surrounding districts; but he is unable to recommend any extensive alteration, and suggests that the lighting of the existing lamps should be increased. He is unable to recommend the purchase of new type lanterns, owing to the expense, as the gas companies are unwilling to let, except on the hire-purchase system, unless for a contract of seven years. He is further credited with the opinion that the present experience of electric lighting for narrow streets—its cost, and, in his judgment, its comparative failure for outdoor lighting, renders the electric light unsuitable for the area over which he is the accredited representative of the Strand Board of Works. After the reading of the report the question of lighting the district was remitted to the Lighting Committee for further consideration.

SWANSEA.—An extensive range of buildings has just been erected by Mr. J. S. Brown at Swansea, and the lighting is

Digitized by Google

throughout by electricity, which consists of nearly 120 incandescents of various candle-power, and eight 2,000-c.p. Waterhouse arcs, as well as two 6,000-c.p. arcs for lighting the glass roof and showroom floors. Rising above the roof is a handsome tower, fitted with a search-light projector. The plant includes a Stockport gas engine driven by an Elwell-Parker dynamo.

THEATRE LIGHTING.—The Prince of Wales' Theatre, at Grimsby, is being lighted throughout by electricity, the installation consisting of about 300 16-c.p. lights, in addition to two powerful arc lamps for exterior lighting. Included in the plant is a 14-H.P. Tangye gas engine.

COMPANIES' MEETINGS AND REPORTS.

Cuba Submarine Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended December 31st last, to be presented at the forty-fifth ordinary general meeting of shareholders, to be held at 58, Old Broad-street, E.C., on Wednesday next, the 14th inst., at 12 o'clock :—

From the accounts accompanying the report it will be seen that the gross receipts (including the balance brought from last account) amount to £23,229. 1s. 6d., and the gross expenditure to £5,069. 16s. 6d., leaving a sum of £18,159. 5s. to the credit of revenue account. Of this the sum of £1,500 has been set aside as a further reserve against any loss from the deposits with banks, and £5,000 added to the reserve fund, making that fund £105,000. The dividend on the Preference shares will absorb £3,000, and leave £8,659. 5s., out of which the Directors recommend the payment of a dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income-tax, the balance, £2,259. 5s., being carried forward to the current half-year, against £2,002. 7s. 6d. at the end of the previous half-year.

The cables have continued in good order throughout the half-year, with the exception of a part of the original cable laid in 1870, between Batabano and Cienfuegos, which gave out at the end of last month ; the other portion of the same cable, between Cienfuegos and Santiago, was abandoned 13 years ago. In consequence of the decayed state of the sheathing, its effectual repair, without renewing the greater part of it, is impracticable, and it has therefore been decided not to spend any more money upon it, but to put down a new cable, the cost of which will be charged to the reserve fund.

The position of the Company's suit against the Spanish Government at Madrid remains the same as at the date of the last report.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The following report is issued by the Directors of this Company, to be presented at the seventh ordinary general meeting to be held at Great George-street, Westminster, S.W., on Thursday next, the 15th inst., at 5 p.m. :—

The district of the parish of St. Mary Abbotts, Kensington, arranged to be purchased from the Chelsea Electricity Supply Company (Limited), was transferred to this Company in June last, the necessary statutory powers having been obtained. As far as can be judged from the experience of one half-year, there is every reason to anticipate a satisfactory result from this addition to the Company's area.

The mains, which extended to a length of 13 miles on December 31, 1892, have been increased during the year 1893 to 16¼ miles—of which increase two miles are due to the new district and 1¼ to extensions of the Company's original system.

During the year the number of houses and shops connected with the system has increased from 550 on December 31, 1892, to 734 on December 31, 1893 ; while the number of lamps calculated on the usual basis of eight candle-power has increased from 47,441 to 64,529. Out of the total increase the new district represents 83 houses and shops, and 5,262 lamps. Thus the increase on the Company's original district is 101 houses and shops, and 11,826 lamps.

After paying the dividends on the Six per Cent. First Preference shares to June 30, 1893, on the Five per Cent. Second Preference shares to September 30, 1893, and an interim dividend at the rate of 4 per cent. per annum on the Ordinary shares for the first half of the year, the balance standing to the credit of the net revenue account for the year 1893 is £4,788. 7s. 9d. Of the above sum £1,456. 4s. 7d. has been appropriated for the payment of the First Preference dividend to the end of the year, and £88 has to be set aside to meet the portion of the dividend on the Second Preference shares to the same date, leaving £3,244. 3s. 2d., out of which it is proposed to pay a further dividend on the Ordinary shares, at the rate of 6 per cent. for the past half-year, making a total dividend for the year of 5 per cent. This will leave a balance of £1,059. 15s. 8d. No provision has been made in the accounts for Directors' remuneration.

In accordance with the Articles of Association, Mr. R. W. Wallace and Mr. A. S. Bolton retire from the Directorship, and, being eligible, offer themselves for re-election. The auditors, Messrs. Lovelock, H. W. Whittle and Dickinson offer themselves for re election.

Newcastle and District Electric Lighting Company (Limited).

The following is the Directors' report, to be presented at the seventh ordinary general meeting, to be held at 57, Westgate-road, Newcastle-upon-Tyne, on Monday next, the 12th inst., at 2:30 p.m. :—

The Directors have pleasure in again reporting that the supply of current continues to give satisfaction to the Company's consumers. The installations connected to the Company's mains during the year are equal to 4,000 10-c.p. lamps, bringing the total up to about 18,500, and 388,422 units of electrical energy have been supplied, as against 290,469 units supplied in 1892. During the past year 3,308 yards of main and branch piping have been laid, together with 6,579 yards of main and branch cable. After some difficulty in carrying through the drift to the river, the condensing plant, referred to in last year's report, is now in operation, and although it has been working only about three months, a considerable saving has been effected in the consumption of fuel and water.

The gross earnings during the year amount to £2,949. 12s. 3d., and after paying interest and making provision for reserve fund and depreciation, and writing off £100 from formation expenses, the Directors are able to recommend a dividend at the rate of 3 per cent. for the half-year ending December 31st (less income-tax), which, together with the interim dividend paid in July last, makes the dividend 5½ per cent. for the year.

Mr. John D. Milburn and the Hon. C. A. Parsons retire by rotation, but are eligible, and offer themselves for re-election as Directors. The auditors, Messrs. Strachan and Co., also offer themselves for re-election.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The following is the Directors' report for the year ended December 31, 1893, to be presented at the thirtieth ordinary general meeting, to be held at the Cannon-street Hotel, E.C., on Thursday next, the 15th inst., at 12 o'clock :—

The accounts show the net profit for the past year to be £94,607. 4s. 2d. Adding £46,844. 17s. 5d. brought forward, and deducting £25,000 interim dividend paid in July, there remains a disposable balance of £116,452. 1s. 7d. The Directors have added £50,000 of this balance to the reserve fund, and recommend the distribution of a dividend of 10s. and a bonus of 5s. a share, free of income-tax, amounting to £37,500, making, with the interim dividend, a total payment for the year of 12½ per cent., and leaving £28,952. 1s. 7d. to be carried forward.

The Company's general business continues to increase. The cable for the Central and South American Telegraph Company mentioned in the last report was duly laid, and a few other cable manufacturing and repairing contracts were carried out during the year. The efficiency of the Silvertown and Persan factories is maintained.

Mr. Scott and Mr. Henderson, the Directors retiring by rotation, offer themselves for re-election.

Newcastle-upon-Tyne Electric Supply (Limited).

The sixth general meeting of this Company was held last week, at the Station Hotel, Newcastle. The Directors' report and balance-sheet having been adopted, a dividend at the rate of 4 per cent. per annum for the half-year ended December 31st last was declared, which, together with the interim dividend paid in July last, makes 4 per cent. for the year.

Sunbeam Lamp Company (Limited).

The annual meeting of this Company was held last week at the offices, Park-road, Gateshead, when an encouraging report of the work done by the firm was presented by the Secretary (Mr. T. J. Grainger), which stated that since the Company resumed operations in November last the factory had been kept busily employed.

On the motion of Dr. J. T. MERTZ, seconded by Miss RICHARDSON, Capt. H. Chapman (Messrs. Clarke, Chapman and Co., Limited) was re-elected Director of the Company.

At the conclusion of the meeting the shareholders and members of the Press made an inspection of the works, under the guidance of the Managing Director, Mr. J. W. Edmundson, and Mr. Grainger.

NEW COMPANIES, STATUTORY RETURNS, &c

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "The Electrician" Electrical Trades' Directory and Handbook, 1894, pages 274-300, &c., &c.]

BRONZE STEEL SYNDICATE (LIMITED).—This Company has been registered with a capital of £6,000 in £1 shares, to carry on business as metallic alloy manufacturers, metal merchants and brokers, steel, iron, bronze and copper manufacturers, &c.

LAS CABESSES MANGANESE MINES (LIMITED).—This Company was registered on February 3rd, with a capital of £250,000 in £10 shares, to acquire the manganese mines and undertaking known as "Las Cabesses," situate in the Department of Ariege, France, now belonging to Charles Simon, who receives 24,000 fully-paid shares as the purchase consideration. The first Directors include John C. Swan, electrical engineer, of Bromley, Kent.

MOSLEY AND CO. (LIMITED).—This Company was registered on February 1st, with a capital of £11,000 in £1 shares, to acquire any patents, licences, concessions, &c., for depositing zinc by electricity or otherwise, upon steel, iron, or any other metal, and to acquire any patents connected with processes for depositing one metal upon another by means of electricity. The subscribers (with one share each) are:—William Thorpe, T. Hainsworth, T. Coombs, W. H. Stocks, J. Day, T. Naylor, and H. B. Farr, all of Leeds.

ELECTRO-PROTECTOR SYNDICATE (LIMITED).—This Company has lately entered into an agreement with Robert Jewell, of 11, Queen Victoria-street, London, E.C., for the acquisition of certain letters patent (particulars of which do not transpire) for £7,000, payable by the allotment, as fully paid, of 7,000 shares, Nos. 3,001 to 10,000 inclusive.

EUROPE AND AZORES TELEGRAPH COMPANY (LIMITED).—The statutory return of this Company, made up to December 28, 1893, was filed on the following day, when 16,700 shares of £10 each out of a capital of £200,000 were taken up. Of these, 5,568 have been issued as fully paid to the Telegraph Construction and Maintenance Company, the contractors for the cable, and a call of £5. 10s. per share has been made on the remaining 11,132 shares, resulting in a total payment of £61,226. The Eastern Telegraph Company hold 5,216 shares, and the Brazilian Submarine Telegraph Company a like number.

EUROPEAN SIMS-EDISON ELECTRICAL TORPEDO COMPANY (LIMITED). The second annual return of this Company, made up to January 14th, has been filed. The nominal capital is £201,000, divided into 10,000 Ordinary shares, of £20 each, and 1,000 Founders' shares, of £1 each. 7,880 Ordinary and 1,000 Founders' shares have been taken up, and 7,350 Ordinary shares have been issued as fully paid. Upon the remaining 530 Ordinary and the Founders' shares the full amount has been called, resulting in the payment of £10,458, leaving £1,142 in arrears.

GENERAL ELECTRIC COMPANY (LIMITED).—The annual return of this Company, made up to January 5th, has been filed. The nominal capital is £60,000, divided into 7,000 First Preference, 1,000 Second Preference, and 4,000 Ordinary shares, all of £5 each. 6,325 First Preference, and all the Second Preference and Ordinary shares have been taken up, the two latter classes being issued as fully paid. The full amounts have been called, and £31. 6s. paid on the First Preference shares. By special resolution passed December 22, 1893, and confirmed on January 8, 1894, the nominal capital was increased to £85,000 by the creation of 5,000 Third Preference shares of £5 each, and certain alterations were made in the Articles of Association.

GENERAL ELECTRIC POWER AND TRACTION COMPANY (LIMITED).—The annual return of this Company, made up to December 26, 1893, has been filed. The nominal capital is £350,000, divided into 25,000 Ordinary and 10,000 Preference shares of £10 each. 23,592 Ordinary and 10,000 Preference shares have been taken up, and 21,734 Ordinary issued as fully paid. Upon the remaining Ordinary shares the full amount has been called, and upon the Preference shares a call of £9 per share has been made. The calls paid amount to £107,985, leaving £595 unpaid.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—The first annual return of this Company, made up to December 26, 1893, was recently filed. The nominal capital is £40,000, in £5 shares, of which 3,396 have been taken up. Upon 3,350 of these the full amount has been called, and upon the remaining 46 shares a call of £2 per share has been made. The calls paid (including a sum of £33 paid in advance of calls) amounts to £16,850, leaving £25 in arrears.

HOLLOWAY ELECTRICITY SUPPLY COMPANY (LIMITED).—When the first annual return was made up (filed on December 12, 1893), only the seven subscribers' shares were taken up out of a capital of £2,000 in £10 shares, and nothing paid thereon.

INCANDESCENT ELECTRIC LAMP COMPANY (LIMITED).—The statutory return of this Company, made up to December 4th, was recently filed. The nominal capital is £25,000, divided into 2,000 Ordinary and 5C0 Deferred shares of £10 each. 1,200 shares have been taken up, and a call of £2. 10s. per share made, resulting in the payment of £2,850, and leaving £150 in arrears.

ISLE OF WIGHT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company made up to September 27, 1893, was recently filed, and shows that seven shares have been taken up out of a nominal capital of £1,000, in £1 shares, no calls having been made.

ITALIAN ELECTRICAL LIGHT AND POWER COMPANY (LIMITED).—The second annual return of this Company, made up to December 22nd, has been filed on December 29th. The nominal capital is £60,000, in £4 shares, of which 307 have been taken up. Of these 300 were issued as paid to Girolamo Taddei, of 83, Via Arenula, Roma, and no calls have as tey been made on the signatories' shares.

CITY NOTES, &c.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY (LIMITED).—The report of the Directors of this Company is issued, and, after dealing with the Company's financial position, the Directors proceed: "We have also concluded our investigations with reference to electricity as a motive power, and we, with confidence, recommend the shareholders to approve the adoption of the overhead system of electric traction on the existing line from Old Market-street to St. George, as well as the proposed extension to Kingswood. The latter district is not only a very populous one, but an important manufacturing centre, and has, up to the present, suffered from want of means of communication with Bristol. We recommend the shareholders to carry out this extension (the Parliamentary powers for which we already possess) if the necessary authority is obtained for the use of electric motive power." The population to be served by this line is nearly 60,000, and the Directors anticipate the hearty co-operation of the Local Boards of the district, as well as the Bristol Corporation. The Company will shortly invite further capital, consisting of 5,000 new shares of £10 each.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended February 4th, were £951, as against £956 for the corresponding period of last year, being a decrease of £5. The total receipts for the half-year amount to £4,790, as against £4,910 for the corresponding period of 1893, a decrease of £120.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of January are £3,900, as compared with £3,876 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January amounted to £1,909, as against £1,901 for the corresponding period of 1893.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of January, 1894, amounted to £64,851, as against £60,516 in the corresponding period of last year, or an increase of £4,335.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January amounted to £39,677 as against £43,040 for the corresponding period of 1893.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for January, 1894, amounted to £21,000. In the corresponding month of 1893 and 1892 they were £20,800 and £20,000 respectively.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—The traffic receipts for the month of December, 1893, were £1,488, and for January, 1894, amounted to £1,682.

MILDE TELEPHONES AND ELECTRIC SUPPLY COMPANY (LIMITED).—As announced in our last issue, a Company has been formed under the above title to trade in the telephones and general electrical apparatus manufactured by Messrs. Ch. Mildé Fils et Cie, Paris. The Company has a capital of £20,000, in Preferred and Deferred shares of £1 each. The offices of the Company are at 60, Watling-street, London, E.C., where prospectuses and forms of application can be obtained.

NEW ELECTRICAL RAILWAY.—For a number of years it has been the ambition of the Directors and shareholders of the London and South-Western Railway Company to bring the present terminus of the line, Waterloo Station, into closer touch with the City. The subject has been discussed times out of number, as the chairman, Mr. Wyndham S. Portal, stated at the meeting of the Company on Wednesday last, but has had to be abandoned as an unprofitable enterprise on which the Company could not afford to embark. The estimated cost of constructing an ordinary railway between the two points, was between three and four millions sterling, and the Directors could not seriously entertain a proposal involving such a larger capital expenditure without seeing their way to get a commensurate increase of traffic. Happily, however, science, and particularly that branch of it which comes under the qualification, electric, has been steadily advancing, and has been invoked to obviate the difficulties which passengers by the London and South-Western Railway have hitherto experienced in getting to and from the City. As our readers are aware, it is now proposed to construct an electric railway from Waterloo Station to a point near the Mansion House, and at the meeting referred to a special resolution was unanimously adopted, empowering the board to proceed at once with the carrying out of the undertaking which, it is calculated, will cost between £500,000 and £600,000. Tenders are to be at once invited. The line, which will be constructed in the course of two or three years, will prove a great boon to residents on the London and South-Western Company's system, and will doubtless prove a source of remunerative traffic to the Company itself.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow 6,832 shares in W. T. Henley's Telegraph Works (Limited) to be quoted in the Official List.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED). Subject to audit of the accounts, the Directors propose paying a dividend of 15 per cent. (£1. 16s. per share), in addition to the 5 per cent. already paid, making 20 per cent. for the year 1893.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—A dividend at the rate of 5 per cent. per annum for the half-year has been declared.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ending February 2nd (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,207.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the two weeks ended January 21st were £2,649, as compared with £3,074 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 822.—Vol. XXXII. FRIDAY, FEBRUARY 16, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The dividends, ranging from 4 per cent. to 5 per cent., which have within the past week or so been declared by some five of our metropolitan electricity supply companies, are in themselves a satisfactory evidence that the business can be made to pay. The steady 12 per cent. of the Gas Light and Coke Company is not, perhaps, altogether to be envied, but whether so or no, it is not, in the nature of things, likely to be attained by an electricity supply company; the day for colossal monopolies of that particular kind are over, at any rate for the present, and gas and internecine competition, and the necessity of making timely provision for the day of purchase, forbid anything in the shape of extraordinary profits. Indeed, there are already some ominous symptoms that the reduction in the cost of production, which is being brought about by experience and large-scale working, is not keeping pace with the rate-cutting policy which was inaugurated last year, and is no doubt destined to continue. There is not much cause to quarrel with the comparatively small sums hitherto generally set aside for depreciation, since the very circumstances of the case require that the plant of an electricity supply company should be kept in perfect repair; but the business will not be in a wholly sound state until, in addition to the payment of a 5 per cent. or 6 per cent. dividend, substantial preparation is made against the day of municipal wrecking—we mean reckoning.

Merely by the way, and not with any desire to make "odorous comparisons," it may be interesting to note how the electricity supply business prospered abroad during 1893. In New York, according to the Report of the Directors of the Edison Illuminating Company, the past year was a most prosperous one. The Edison Company has now the equivalent of nearly 400,000 8-c.p. lamps connected to its mains, not to mention 2,500 arcs and motors to the extent of over 5,500 H.P. The net earnings of the concern for 1893 were £121,128, an increase of 27 per cent. over those for 1892. In Paris the Compagnie Continentale Edison reports a profit for 1893 of £101,340, an increase of 21 per cent. over the figure for 1892. In Berlin the Elektricitätswerke, which has a lamp connection of 328,000, has paid an 8½ per cent. dividend, and put £5,200 to the reserve and renewal funds.

It is gratifying to note the steady progress and continued success of the two great electric traction enterprises in this country—the City and South London Railway and the Liverpool Overhead Railway. Of the two the latter has by far the more favourable position, and yields the more satisfactory results. During the past six months the Liverpool line, the numerous stations on which skirt the docks, has carried passengers at the rate of five millions per annum. According to the Report presented at the shareholders' meeting last Tuesday, the gross earnings for the six months were £18,518, and the working expenses for this period £13,732, by which it will be seen that both in efficiency of plant and in carefulness of management a very satisfactory condition of affairs obtains. The number of trains run during the stated period was 46,429, of which 95·35 per cent. were stated to be "on time." Items like this, though some engineers might not admit it, are quite as important to the success of a railway scheme as the question whether the low-pressure cylinders at the generating station ought or ought not to be jacketted. Public confidence is worth a good many pounds of steam, and statistics such as the foregoing confirm us in the belief that electric traction of this class can be made a sound financial success, and can be made to compete without fear, under these or similar conditions, with any existing system of railway traction.

Prof. H. Robinson's Paper read before the Society of Arts on Wednesday last, and printed in abstract in our present issue, gives only a general account of the St. Pancras supply system, and was intentionally written only on broad lines. Little or nothing, unfortunately, was added in the discussion, for the author declined to give information even on such small but interesting details as the air-pressure maintained in the culverts by the ventilating fan. This, and the cost of pumping, &c., for condensing, he promised for a future communication. Mr. A. Siemens made a few remarks, and observed that as the new sub-station was 2,700 yards distant from the station, the three-wire system was easily adapted for a two-mile radius. Mr. Kapp somewhat surprised the audience by speaking of the difference between the coal consumption per unit sold per annum and the consumption estimated from tests of the dynamos at Thames Ditton, as a mystery. The difference was indeed large, since Prof. Robinson's figures work out at about 12lb. per unit. Mr. Kapp gave a few figures about Bristol. There are 11 sub-stations, the supply extends over two miles, and further extension is demanded. Lead-covered iron-armoured cables are used, 12,000 lamps are connected, and the coal works out at 12lb. per unit. The most interesting contribution to the discussion was from Mr. Eccleston

Digitized by Google

Gibb, who gave an account of the action of the County Council in connection with loans to municipal authorities. Justice cannot be done to these remarks in a brief abstract, and we hope to give them in a more complete form on another occasion.

The Victoria Embankment lighted by the Metropolitan Board of Works in 1884 under an agreement with the Jablochkoff Company is to be taken in hand shortly by the County Council. The Highways Committee recommended that poles should be set in the middle of the road, a proceeding which Colonel Ford, for some inscrutable reason, thought would be "for the inconvenience of the vast masses of the people who used Waterloo and Westminster Bridges." That £2,000 might be thus saved appealed to several members, but fortunately this proposed disfigurement was abandoned. Posts in the middle of the road are all very well where there is plenty of room, and where, as in Tottenham Court-road and other places, there is no view to spoil. We regret, however, that it has been suggested to place the lamps on alternate sides of the Embankment roadway. This is quite unnecessary. The lighting in 1884, from the lamps on the parapet, was, as far as distribution is concerned, excellent. The traffic in the late afternoon and evening is almost entirely westwards, and, therefore, on the river side. A single sweep, more than a mile and a-quarter long, of close-set six-ampere arcs on the present posts would have a fine effect. Elaborate as is the ornament on the City posts, as disclosed in the illustrations in Gen. Webber's Paper, but hardly noticed in the streets, the general appearance is ugly, and not much more can be said for the posts at Brighton, or for the German ironwork at Oxford. Ten-ampere lamps on high posts at long intervals are cheap, but they would spoil the Embankment, of which, but for such hideous buildings as King's College and Charing Cross Station, all Londoners are particularly proud.

A curious want of proportion exists between the length of the report of the inquest on the lad who was killed at Prescot, through meddling with high pressure wires, a fortnight ago, and the report furnished to the Board of Trade by its electrical adviser on the accidental death of a grey mare at Bournemouth. Twelve honest men with a newspaper knowledge of electric lighting are supposed to be competent for the former case, and if they think fit, to suggest precautions which ought to be adopted. But it must not be supposed that the Electrical Department is so well equipped that, like the Railway Department, an inspector can be sent off at an hour's notice to report upon every accident. So willing is it, however, to serve the public that when the Bournemouth Town Council telegraphed for advice, Major Cardew was on the spot within twenty-two hours of the mishap. The curiously high insulating character of the soil, and "the juxtaposition of masses of thawed and masses of frozen ground," seems to have caused the current to rise from one leak to the surface, to pass along the wet surface, and to descend to the other leak. Such a combination of circumstances must, of course, be very rare. The iron pipes in which the conductors are drawn ought to have been bonded together with a metallic connection. This is the practice at Bournemouth, but it had been neglected in this one instance. A question asked in the House of Commons on Monday shows that there is a natural fear that human life may be endangered by such accidents. This matter may confidently be left with the Board of Trade. It may be remarked that the shoes of a horse make an exceptionally good contact, and this particular one was pre-disposed by a weak heart. On one occasion, at Berlin, a man laid his hand on a horse's back and experienced only a slight shock, while the horse fell stone dead.

When, about three years ago, a scheme was announced for building a locomotive on which a high-speed engine was to drive a three-phase alternator, which was in turn to drive motors, it met with a little ridicule, and the two sets of tests which have been recently made on the Chemin de Fer l'Ouest at Havre have raised a smile, but only where the reasons for this roundabout system have not been understood. The two chief difficulties in obtaining higher speeds than from 70 to 80 miles an hour with ordinary express locomotives are want of balance and want of space. A good rotary engine would get over the first disadvantage, but want of space would become a more serious difficulty than at present if an attempt were made to mount such an engine direct on the axles. The impossibility of avoiding the superfluous vertical action of balance weights on an ordinary single-wheel locomotive is alone sufficient to reduce the adhesion and to allow slip at speeds a little over 80 miles an hour, and a driving wheel 8ft. diameter, running at 60 miles an hour, only makes 210 revolutions per minute. Another drawback to a locomotive as commonly built is that the direct connection between its speed of travel and the speed of the driving wheels actually checks the full output of the engine on a gradient at the time when maximum power is wanted. All these difficulties are reduced, if not avoided, in the Heilmann locomotive, though not without the introduction of others, and it remains to be seen how the balance of advantages works out.

The idea of using a three-phase alternator was soon abandoned, as more or less synchronism was necessary, and this was one of the things to be avoided. The absence of commutators and brushes appears to be the only argument in favour of alternating currents for such a purpose. A compound horizontal steam-engine, with cylinders on opposite sides of the crank shaft is designed to develop 600 H.P. at 300 revolutions per minute. It may be observed that this engine provided with 8ft. driving wheels would travel at about 86 miles an hour at this speed. It is, however, mounted across the locomotive, and drives a dynamo made by Brown, Boveri & Cie., giving over 1,000 amperes at 400 volts; another small engine drives an exciter. The dynamo has six poles and a Gramme-ring armature. There are eight motors, four on each bogie; they have four-pole cast-steel fields boxing in the armatures, each takes 125 amperes at 400 volts, and these eight can, of course, be easily connected in groups of two or more in series. The speed of the test runs has been restricted by the railway company, and, according to the *Temps*, the return

journey from Beuzeville to Havre on Saturday last, including a long up gradient of 1 in 125, was made at 100 kilometres, or 62 miles an hour. The weight of the train on the previous test was a little under 200 tons. We have not heard to what extent vibration has been reduced; that part which is due to the engine should be small, but jumping due to irregularities of the road still remains, and though no doubt it is well to experiment with a high-speed locomotive first, such a machine will be of little use until a suitable line has been laid.

We give to-day, in another column, the conclusion of our abstract of the Paper on "Telegraphic Communication between England and India," recently read by Mr. E. O. Walker before the Indian Section of the Society of Arts. Considering that Mr. Walker was an official in the Indian telegraphs, it is somewhat surprising that so many of his statements should be inaccurate and his deductions misleading. Want of space compels us to refer to a few instances only. He states that the land lines and cables can each transmit fifteen words per minute, and implies that with duplex this carrying capacity is nearly doubled. As a matter of fact the number of paying words which can be sent over the long cables, with duplex working, between here and India is nothing like thirty a minute, being considerably less than half that number. Then he assumes that 4,000 messages could be transmitted between 11 a.m. and midnight without delay, which means that the telegrams would steadily flow into the offices nearly as fast as they could be sent off. Mr. Walker surely knows that telegrams are not so obliging, and come in with a rush at certain hours. The fact is, there must always be a large reserve of carrying power in telegraphy to prevent delay and provide for interruptions. To promise the Companies £1,750,000 a year by carrying out his suggestions is like assuring railway companies that if they only lowered their fares every seat in every train despatched would be occupied between, say, 8 a.m. and 9 p.m., and telling them what their earnings based on such a traffic would be. Mr. Walker says that the cost of the Persian Gulf cables, which belong to the Indian Government, is an important factor in determining the rate to India. Does he assume that cables in the Red Sea and Indian Ocean, which do not belong to the Indian Government, are inexpensive, and, consequently, not important factors in the matter?

The article on Electrical Units which we publish this week is a useful contribution to a subject about which much confusion still exists. Nearly thirty years ago the British Association started the work of arranging a consistent system of electrical units, founded on the fundamental units of length, mass, and time. The ablest electricians at home and abroad have assisted from time to time in this endeavour, and their labours may be said to have ended with the Congress held in Chicago last autumn. The result is one of which every electrician can be proud, and there can be little doubt that weights and measures founded on this international system will be ultimately adopted by civilised nations to replace the arbitrary systems now in use. Nevertheless, this result has not been brought about without the introduction of many confusing considerations, which would certainly have been avoided if each country had adopted a simple arbitrary system of its own. In the first place, it has apparently been necessary to consider three distinct systems of units, called the electromagnetic, the electrostatic, and the "practical." The last system consists of units, each of which is an arbitrary multiple or sub-multiple of those of the former system. The second system is only wanted for theoretical work in electrostatics, and is hardly ever used. Its connection with the first system is never clearly explained in text-books, and its omission altogether from such books would be a positive gain as regards the student.

The system of units established by the British Association is as perfect theoretically as anyone can expect to be adopted; but even from a theoretical point of view it is possible to point out improvements. Mr. Heaviside has done so in these columns, although there can be little hope that his "rational" system of units will ever receive much attention except from theorists. It is, however, from the practical side that most confusion about these electrical units has been caused. The ohm standardised by the original Committee of the British Association, and called the B.A. unit, was found to be wrong by more than one per cent. This error was to a great extent corrected at the first Paris Congress, and so-called "legal ohms" were introduced. These, in turn, were found slightly wrong, and after much confusion about legal ohms, real ohms, Rayleigh ohms, and various other ohms, the true and only ohm, which is to be the British legal ohm, has been discovered by a committee of the Board of Trade, and has been recently christened in America as "International."

The difficult points of theory, alluded to by Mr. R. M. Deeley in our Correspondence columns this week, will probably remain unexplained until more definite information is forthcoming as to the interaction between ether and matter. It is possible for steady states of electric or magnetic force to exist independently of each other, but it is not possible for an electric field, varying with time, to exist without giving rise to a magnetic field, and *vice versâ*. A varying magnetic field gives rise to induced electromotive forces, while a varying electric field induces magnetic forces. This does not imply, of course, that the induced forces, whether electric or magnetic, are of appreciable magnitude, so that an undulatory electrical disturbance, although giving rise to an undulatory magnetic wave, may still remain practically a purely electrical phenomenon. Electrical waves may in this sense be either electric or magnetic, according to the relative importance of the electrical or magnetic undulations. Every wave, however, must be electromagnetic, since both kinds of disturbance must be taking place, and the undulations which comprise light must also be electromagnetic, although it has been made nearly certain by recent experiments that the undulations referred to in the higher parts of the wave theory of light are those which correspond with the electrical disturbances in an electromagnetic wave.

The General Electric Company of America.—Prof. Elihu Thomson is reported to be contemplating the starting of an electrical manufacturing company of his own.

The Glasgow and West of Scotland Technical College.—The Glasgow University Court, at their meeting on the 8th inst., agreed to recognise the day Lecture and Laboratory Courses delivered by Prof. Jamieson on Electrical Engineering as qualifying *pro-tanto* for Graduation in Science under Section IV. of the Ordinances regulating Degrees in Science in Engineering.

Newport.—At the meeting of the Town Councll on Tuesday last it was finally decided to accept the tender of Messrs. John Fowler and Co. for all the electric lighting plant except engines and cables. The order for the former was given to the Uskside Engineering Company, and for the latter to Messrs. Siemens Bros. and Co., "subject to the cables being made in England."

Thunderstorm at Burnley.—At Burnley a severe thunderstorm was experienced last Monday, and while at its height a tall chimney at Towneley Colliery, belonging to Lord Crawshaw, was struck by lightning. One half of the chimney was completely shattered, and the discharge passed down the pit shaft, which is 300ft. deep, curling up the metals at the bottom. Bricks from the chimney fell in all directions, and two men were injured.

The City of London Electric Lighting Company.—We are glad to receive from the manager and engineer of the Company, in response to the suggestion we made last week, returns of the lamp connections of five dates during the past two years. These, plotted on the diagram published in our last issue, show a most satisfactory progress, resulting in a total at the end of 1893 of 65,341, nearly 1,000 more than the lamp connections of the Kensington and Knightsbridge Company.

Obituary.—The death is announced, within two days of his 90th year, of Mr. John Galloway, one of the founders of a great engineering business at Manchester, and known in commercial circles as "the father of the Manchester iron trade." One of his sons is chairman of Galloways (Limited), the company by which the works of the late Mr. Galloway and his partners is now carried on.——The death is also recorded of Mr. John Hick, J.P., one of the founders of the large engineering firm of Messrs. Hick, Hargreaves and Co., Soho Iron Works, Bolton.

Derby.—While calling our attention to the fact that in *The Electrician*, February 9th, p. 367, his name had been misspelt, Mr. J. E. Stewart informs us of the progress which has been made in the lighting of Derby. Since the opening of the central station at that town, on October 10th last, 2,600 8-c.p. lamps have been connected to the mains, and 37 additional lamps have been placed for street lighting. It is expected that another 2,800 lamps for private consumers will be ready for use shortly, and that another 30 street lamps will be fixed.

The Ventilation of Electrical Conduits.—In a paper recently read before the Glasgow Physical Society, the author (Mr. William Lackie, electrical inspector to the Corporation) gave it as his opinion and experience that no ventilating system was requisite, and stated that although in Glasgow nearly 500 manholes existed, only in six of them had any trace of gas been discovered, and then only owing to damage to the gas-pipes caused by the extensive railway operations being conducted throughout the city.

Exhibition of Meteorological Instruments.—The Council of the Royal Meteorological Society have arranged to hold, at 25, Great George-street, S.W. (by permission of the President and Council of the Institution of Civil Engineers), from April 10th to 20th, an Exhibition of Instruments, Photographs and Drawings relating to the Representation and Measurement of Clouds. The committee will also be glad to show any new meteorological instruments or apparatus invented or first constructed since the Exhibition in 1892, as well as photographs and drawings possessing meteorological interest.

Gas-Retort Carbon for Anodes.—In the preparation of chlorine and caustic soda by electrolysis, one great source of trouble is the difficulty in getting anodes which will not corrode. The Electrolytic Caustic Soda and Chlorine Trust, of Snodland, Kent, have found that, after all, the best material is gas retort carbon. They cut out a part of the carbon and fill in with lead; but this lead is not to dip into the electrolytic solution. This, says the *Gas World*, again illustrates the advisability of attention being paid to getting gas-retort carbon in slabs rather than in lumps, for the purpose of making electrodes.

The Bournemouth Accident.—In the House of Commons, on Monday evening, Mr. Weir asked the President of the Board of Trade whether his attention had been drawn to a serious accident which occurred in a public street in Bournemouth on the afternoon of the 8th inst.; whether the accident was caused by a leakage of high-tension electricity from the electric wires laid under the street; and whether steps would be taken to prevent similar accidents occurring in the streets of London, where so many high-voltage systems were in constant use under the thoroughfares. Mr. Mundella stated in reply that the Board of Trade was considering whether any additional regulations were necessary in order to prevent similar accidents in future.

British North Borneo and Telegraphy.—Speaking at the meeting last week of the British North Borneo Company, Mr. R. B. Martin, M.P., who presided, said that the Eastern Extension Telegraph Company hoped to land their cable at Labuan, which would practically connect North Borneo with Singapore and Europe, by the end of April next. He need not say that this would be a great boon not only to themselves but also to the various companies working in their country. The cable was leaving very shortly, and when once the expedition arrived on the spot it would only take a few weeks to lay. He therefore hoped that long before their annual meeting in June next they would be able to report the establishment of telegraphic communication with their territory.

Electricity Supply in Sweden.—In the 1893 report of the Elektron Lighting Company of Gothenburg it is stated that this Company's station is on the three-wire system. The dynamos are run in pairs, and rope-driven from engine fly-wheel. The larger ones are by Crompton, the smaller of Swedish make. The boilers work with forced draught, the air being blown into the closed ashpit by an ordinary blast fan worked by separate engine. The cables (Callender Bitumen) are all overhead. The lighting embraces 28 1,400-c.p. arcs for the harbour lighting, 51 arcs for shop lighting, and about 5,600 16-c.p. and a few 5, 8, 32, and 50-c.p. glow lamps for shop and private lighting, in addition to which the station supplies current to some 20 motors, ranging from $\frac{1}{4}$ H.P. up to 8 H.P., aggregating about 45 H.P. The service is continual, day and night, all the year round. Most of the current is sold by contract, and the energy actually generated amounted to 457,908 units, the total income for which was £4,544, or 2·38d. per unit sold.

Bradford.—At the last meeting of the Town Council, Alderman Moulson, chairman of the Gas and Electricity Supply Committee, in moving the adoption of the report, said that the electricity works were in fairly good order. During the half-year the sales of electricity came to £5,510, as against £4,548 in 1892; the total outgoings were £4,463 against £3,562 in 1892. The total amount of the capital was £56,679. The total number of lamps connected was 28,400. There would have been in connection with the electricity works a very good profit had it not been for the coal strike, which had made the coal cost about £600 extra. Alderman F. Priestman, at the close of the statement, expressed the opinion that it would be a very great advantage to the Corporation to reduce the price

Digitized by Google

of electricity to 2½d. or 3d. for motive power only during the day. He had reason to know that people who were using a considerable amount of current would not go on paying 5d. for it, which was a higher price than they were giving for other motive power. The minutes were adopted.

Official Vocabulary for Code Telegrams.—The Secretary of the General Post Office notifies intending users that the International Bureau at Berne will shortly issue this vocabulary, and points out that the employment of these words will become compulsory for European code telegrams after the expiration of three years from the date of its publication, and that its general adoption for the extra-European messages is desirable. The vocabulary will consist of about 200,000 words drawn from the eight authorised languages. The circular omits, however, to point out that the compulsory use of the words for extra-European telegrams is left for the decision of the next Convention, which is to be held at Buda Pesth in 1896. There is no doubt, however, that the compulsory use of the Authorised Code Vocabulary will then be decided upon. The price per copy of the book will be 10s., and copies will be supplied through the Post Office. Intending subscribers are invited to forward applications to the Secretary of the General Post Office. The circular is dated January 15th, but is still being sent round by the Department.

The Electric Lighting of the Embankment —At the last meeting of the London County Council the Finance Committee recommended that the work of laying the necessary conduits and forming the refuges round the lamp columns in connection with the electric light installation for the Victoria Embankment, &c., be carried out by the Council without the intervention of a contractor. The chief engineer estimated the cost of this preliminary work at £2,100. Mr. Lloyd moved a reference back. The lamp-posts proposed to be put in the middle of the roadway greatly impeded the traffic, as had been shown in Euston-road. Mr. Beresford-Hope seconded. The Embankment was one of the finest thoroughfares in the world, and to put posts in the centre would spoil it utterly from an æsthetic point of view, besides interfering with the traffic. Mr. Bassett-Hopkins hoped the Council would not listen to the arguments of the two previous speakers. To put the posts—which would be handsome columns—on the side paths would add £2,000 to the cost. Mr. Roberts supported Mr. Lloyd's amendment. Was the Council going to spoil the Embankment for the sake of £2,000? The posts which had been put up by the St. Pancras Vestry certainly did not add any adornment to the roadway. Mr. Torr thought it was desirable to keep the traffic in two strings, which would be effected by placing the posts in the middle of the road. After some further discussion the amendment to refer the matter back was carried on a vote.

The Harness Case.—Mr. Richard Furber, of 8, Gray's Inn-square, has forwarded the following letter to Messrs. Lewis and Lewis, Mr. Astor's solicitors, giving Mr. Harness's reasons for discontinuing his action against the *Pall Mall Gazette*:—

"Dear Sirs,—I have been consulted by Mr. C. B. Harness with reference to the pending action for libel brought by him in respect of the articles which appeared in the *Pall Mall Gazette* in the month of October last. You are aware that Mr. Harness has recently, and after he had commenced that action, been prosecuted for a conspiracy to defraud and obtaining money by false pretences, as suggested in the columns of the *Pall Mall Gazette* containing the libels referred to, with the result that after sixteen days' hearing, extending over a period of three months, he has established his innocence of the charges made against him, the magistrate having dismissed them after hearing only a small portion of the evidence for the defence. The costs of his defence during this prolonged investigation have been very heavy, and my client, who is erroneously supposed to have made a considerable fortune out of the business of the Medical Battery Company in which he is interested, and in which all his capital was invested, finds his resources entirely crippled, and is therefore unable to find funds (which must necessarily be very large) to carry on this litigation against your client, who is a millionaire, and to whom money is probably of no object. I feel that he would, under the circumstances, be carrying on the fight on the most unequal terms, and, having vindicated his character in a court of law from the serious allegations made against him in the *Pall Mall Gazette*, as distinguished from the vulgar abuse which accompanied them, he has determined, on my advice, to discontinue the action. I enclose formal notice of discontinuance. This is a course which he takes with the utmost reluctance, yielding only to advice which has been given him on the assumption that your clients will loyally accept the decision of the magistrate, who stated in his judgment that he had been convinced against his inclination that the charges were without foundation."

Northern Society of Electrical Engineers.—At a meeting of the Northern Society of Electrical Engineers in Manchester last week, Mr. John Hesketh, of Blackpool, read a Paper on the Blackpool Central Station, with a view to provoking a discussion on the broad question of central station designs. Mr. Hesketh gave details of the plant, and fully described the method of distribution, which is by means of cables insulated by vulcanised india-rubber. As many as six cables were drawn into 3in. cast-iron pipes, and over 20 miles had so far been laid, the furthest point at which a supply was given being two miles distant from the station. It was not, he said, his intention to go closely into the question of the cost of working the plant at Blackpool. The time had not been long enough for a reliable deduction to be made on this head, and he would, therefore, reserve the question of cost of working for a future communication. The point of discussion he desired to raise by the Paper was, given an area of supply such as Blackpool, with two classes of lighting, what general design of station was best calculated to give satisfaction? The only question likely to be raised was that of general efficiency and reliability, and he strongly inclined to the opinion that reliability was worth the sacrifice of a percentage of efficiency ranging from 5 per cent. upwards. The question of distribution was one having many aspects. The advocates of the simple two-wire system had now many opponents, but with a high-tension network designed to feed each transformer from two directions, and with banked transformers feeding into a similar low-tension network, the variation in voltage, which, after all, was the public's criterion of successful lighting, was reduced to a minimum. The question of mains and their insulation, too, was viewed differently by different engineers. His own opinion was that it was useless to endeavour to lay watertight conduits, and that the endeavour should be to have cables to run as well in water as out of it.

Proposed State Telephones in Norway.—The Norwegian Telephone Committee has, says our Scandinavian correspondent, now ended its labours, and the report recommends some very extensive alterations of the whole telephonic system of the country, based upon exhaustive examinations and calculations. The main points of the report are as follows:—The State takes over the building and working of both local and long-distance telephone lines, and obtains, by degrees, possession of the existing private telephone companies, either by purchase by private contract or by expropriation. Long-distance telephones are to be constructed, having Christiania for their centre, in accordance with a plan already completed. According to this plan some half-dozen long-distance telephone-lines shall be taken in hand; among these are lines to Frederikshald and the frontier, along the coast to Bergen, *viâ* Thelémarken to Bergen, with various branch lines, to Drontheim, and on to Namsos, &c. This plan only refers to that part of the country lying to the south of Namsos. At the same time concessions will be given to private individuals or syndicates for the erection of telephone lines at places where the State either has not built or does not intend to build telephone lines. Private telephone companies are to be allowed to have connection with the State telephones, and the telegraph stations will everywhere be connected with the respective central State telephone stations. Both local and long-distance lines are to be constructed on the twin-wire system; the single-wire telephone companies, which the State may acquire, are to be gradually transformed into double-wire concerns. The following annual charges are recommended:—For Christiania, £5. 10s.; for Bergen and Drommen, £4. 9s.; for Drontheim, Stavanger, &c., £3. 6s. 6d.; for other towns, £2. 15s. 6d. These are all for twin circuits. The charges for conversations on long-distance lines are regulated according to the distance between two neighbouring towns, about 3d.; for distances up to 100 miles, 6⅔d.; for distances over this, 1s. 1d. The length of a conversation to be three minutes. The expenditure is estimated as follows:—Purchase of existing telephone companies south of Namsos, 2,630,000kr.; altering of these to double-wired, 1,840,000kr.; new lines, 2,112,000kr.—6,285,000kr., or, with incidental expenses, 7,000,000kr., or about £350,000. The estimated net profits amount to 320,000kr., or about £16,000, per annum—that is to say, 4·6 per cent. on the capital.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 381.*)

Thermodynamic Principles.

Notes on Some Physical Effects of Heat.—One of the most palpable of the effects of heat on matter is the tendency of the heated body to communicate its heat to surrounding objects. This effect is called *temperature*. Any body is said to be at a higher temperature than any other body when there can be a direct transfer of heat from the former to the latter without that heat being transformed in its passage into any other form of energy. By this it is meant that while a body can supply heat to one that is hotter by indirect energy transformations, as when a steam engine makes arc lamp carbons hot, it is impossible for heat to flow directly from a colder to a hotter body. When heat cannot be made to pass in either direction between any two bodies, these may be defined to be at the same temperature; and this definition is independent of the system upon which the temperature may be measured. Temperature is measured upon several systems, of which two are used in engineering: (1) the volumetric system, and (2) the thermodynamic system. The volumetric, or ordinary, system is based upon the expansion of bodies when a rise of temperature takes place in them. The thermodynamic system is based upon the work which may be done by heat passing between the two temperatures which are compared. In the Fahrenheit scale of ordinary temperatures two points on the scale are fixed by the melting point of ice and the liquefying point of steam (at standard pressure) respectively. The former is marked 32 degrees and the latter 212 degrees; an interval of 180 degrees occurring between them. These successive degrees of temperature are recorded on the thermometer scale by the expansion of a mass of mercury, contained in a bulb at the base of a sealed and graduated capillary tube. Equal increments in the height of the mercury in the tube are assumed to represent equal increments of temperature. In the air thermometer, of which more will be said presently, the successive degrees of temperature are determined by equal increments in the volume of a portion of air heated in a confined space at constant pressure. It therefore by no means follows that equal increments of temperature, as measured volumetrically by the expansion of an arbitrarily chosen substance such as mercury or air, will be a correct representation of equal increments in the heat-energy state of the heated body. But it will presently be shown that the ordinary scale of temperatures is practically identical with the scale in which equal degrees represent equal increments of heat energy of some perfectly elastic substance.

If we take a rod of some solid substance, such as iron or copper, and raise its temperature, we find that it has increased in length. It has also expanded in the same proportion in every other direction. If we measure this linear expansion of the rod, we find that it is practically proportional to the rise of temperature of the rod as measured on a mercury thermometer; provided always that the rise of temperature is not sufficient to alter the other physical properties of the rod. The volumetric expansion is approximately three times the linear and the surface expansion twice the linear. If, now, instead of causing the rod to expand by heating it, we elongate it by the application of a tensile stress; or if, instead of causing it to contract by cooling, we cause it to become shorter by means of a compressive stress; we shall produce a similar linear change in the rod. The expansive or contractile effect of change of temperature may therefore be measured in terms of an elastic force which would produce the same result. It is popularly supposed that the elastic force of expansion of solids is infinite and irresistible. This is erroneous: for if we raise the temperature of a rod or other shape of solid, at the same time so constraining it that it cannot freely expand, we shall set up within the body compressive stresses of equivalent value as determined by the elasticity of the body. This is an important point, as it affects the behaviour of structures which are so heated as to be unable to freely take the proper shape which their rise of temperature would naturally produce. In the following table (V.) the coefficients of expansion of some important metals, together with the equivalent values of these coefficients, considered as elastic stress in lbs. per square inch section, have been tabulated. The coefficients of expansion give the fractional increase of length per 1° F. rise of temperature:—

Table V.—*Linear Coefficients of Expansion and their Equivalent in Elastic Stresses.*

Metal.	Coefficient of Expansion per 1° Fah.	Equivalent Stress in lb. per sq. in. per 1° Fah. (from Young's modulus)
Steel (rod and boiler plate)	0·00000636	165
Steel (cast)	0·00000636	190
Wrought iron (rod & plate)	0·00000680	197
Cast iron	0·00000617	142
Brass	0·00001042	102
Copper	0·00000960	144
Gun metal	0·00001060	106

As an example we may cite the case of a rod or tube of wrought iron subjected to a rise of temperature of 100° F., the metal being prevented from elongating. A stress of 19,700lb. per square inch would result—a stress far beyond the safe working stress of this material. As a matter of fact, no substance under stress can be perfectly constrained; but, in practice, stresses will arise in proportion to the degree of constraint. Where any detail is liable to undergo very great variations of temperature, this matter becomes one of some importance.

The heat which is supplied to the rod of iron or copper, about which we have been speaking, is expended in two ways:—(1) In raising the temperature of the rod; (2) in expanding it. The former of these is usually called the *sensible heat*, the latter the *latent heat*. Sensible heat is measured as the product of the true specific heat of the substance into its temperature. Latent heat is in reality not heat at all, but potential energy. If we exert mechanical force in elongating a rod of metal, we must necessarily expend energy and do work. Of the total heat put into any body which expands under the process, some at least must be expended in doing this work of expansion—in overcoming the elastic resistances of the material—and this portion is called latent heat. If, to cite another case, instead of taking a rod of metal we supply the heat to a block of ice a few degrees below the melting point, we find that both rise of temperature and expansion occur till 32° F. is reached. Then all the heat which is afterwards supplied becomes latent, the ice melting at a constant temperature. As soon as the ice is all melted the added heat again becomes partially sensible, and the temperature rises until the boiling point is reached. At this last-named point all the added heat again becomes latent, being expanded in turning the water into steam at a constant temperature. Beyond the point where all the water is turned into steam, the addition of heat will cause a rise of temperature, and heat will become latent only if the steam is allowed to expand. Latent heat is, therefore, associated with the physical change of state of any substance, and represents the work done in producing that change.

The term specific heat is given to the number which indicates the amount of heat which is required to produce a rise of temperature of 1 degree in unit mass of any substance, the unit of mass being either the gramme (in the c.g.s. system) or the pound (not the 32lb. of the engineering system). It is evident that this coefficient may be regarded in two ways: first, in relation to the total heat which must be supplied to the unit mass; second, in relation to the fraction of the total heat which alone is employed in raising the temperature of the body. In the first the coefficient is called the *apparent specific heat*, in the second it is called the *true specific heat*. In solids and liquids the difference between the two coefficients is very small and may generally be neglected; but in gases the rate of expansion is so great that a considerable difference may arise.

The volume of a gas is determined by its mass, its pressure and its temperature. The volume of any given mass of gas has been found by Boyle to vary inversely with the absolute pressure to which it is subjected, when the temperature of the gas is maintained constant. This is known as *Boyle's law.* Since pressure alone will affect the volume of a gas, it will be necessary to notice the variation of pressure in any determination of the effect of a change of temperature on the volume. Charles has found that when the absolute pressure of any mass of gas is kept constant, its coefficient of expansion as referred to the volume of the gas at any standard temperature, is constant and independent of the chemical nature of the gas. Thus, if we take the zero on the Fahrenheit scale as the standard, it was found by Charles that all gases expand 1/460 of their volume at this temperature when raised from any temperature to a temperature 1°F. higher. Conversely, if the gas be cooled it will contract 1/460 of this standard volume for each 1°F. of cooling. So that if any gas could be cooled down to a temperature 460°F. below the ordinary zero, remaining a gas all the while, it would completely lose its volume. The temperature −460°F. is therefore called the absolute zero of temperature on the Fahrenheit scale. Absolute temperature is measured by the number of degrees on any scale reckoned from the absolute zero; and on the Fahrenheit scale is equal to the ordinary Fahrenheit temperature + 460. The law of expansion of gases at constant pressure may therefore be expressed by saying that the volume of any mass of gas at constant pressure is directly proportional to its absolute temperature. This is known as *Charles's law.* Let V be the volume of any portion of gas at any absolute pressure, P, and absolute temperature, T; and let V_1, P_1, and T_1 be the volume, pressure and temperature of this portion of gas under other conditions. Then by Boyle and Charles's laws,—

$$\frac{V \cdot P}{T} = \frac{V_1 \cdot P_1}{T_1} = \text{a constant.} \quad . \quad . \quad . \quad (38)$$

Any substance which would behave according to the foregoing expression for every possible set of conditions would be a perfect gas. No such substance is known in nature. All known gases tend to become liquid at very low temperatures and great pressures; and when they approach the liquid state they pass through a state of vapour, in which the viscous forces within its substance cause the law of its expansion to depart more and more from the above simple expression as the liquefying point is approached. Many gases, however, behave as perfect gases within certain limits of temperature and pressure, where the conditions are far above those which would liquefy the substance, and below those which would decompose it. Air and all gaseous products of combustion follow this law at furnace temperatures.

The passage of heat from a hotter to a colder body is effected in several ways. Of these, the only direct ways in which the heat remains as heat during the transfer are *conduction* and *convection.* In conduction, the heat is passed along by communication of heat between contiguous portions of the conducting body. In convection, it is passed along by the actual transfer of the heated body itself. Besides these direct modes of transfer, heat is frequently passed from a hotter to a colder body by reason of the former setting up ether waves in the space surrounding it, which waves, in their passage from the hot centre outwards through space, are partially intercepted by the cooler body, and their energy partially turned back again into heat in the latter. This most frequent mode of passing heat energy from a hotter to a colder body is called *radiation*, and the energy of the ether waves is called radiant energy.

The number of units of heat conducted through any body varies directly as the continued product of the difference of temperature between the ends of the path along which the heat must flow, the section of the path, the time during which the difference of temperature is maintained, and a constant called the specific conductivity of the material, and it varies inversely as the length of the path along which the heat must flow. Thus, if T_2 is the temperature of the hotter end, and T_1 that of the colder end, while L, S, t and K are the length, section, time, and specific conductivity respectively, the flow of heat by conduction will be—

$$H = \frac{(T_2 - T_1)\, S . t . K}{L} . \quad . \quad . \quad . \quad . \quad (39)$$

Since in furnaces heat usually passes through conductors of plate shape, it will be convenient to measure the section or surface exposed to heat in square feet, the length of the plate or thickness of the plate in inches, and the temperature and time in Fahrenheit degrees and hours respectively. The values of K on this system are given in Table VI.:—

Table VI.—*Specific Thermal Conductivities of Solids, in B.T.U., transmitted per hour through 1 in. thickness and 1 sq. ft. surface, with 1°F. difference of temperature.*

Substance.	K	Substance.	K
Copper (sheet)	555·0	Porcelain	56·0

Glass	70·0	Hair felt (wood lagged)	0·72
Stock bricks	63·0	Wood ashes (loose)	0·56
Asbestos	56·0	Eiderdown	0·50

The difference of temperature between the opposite surfaces of the materials tabulated in the above table is supposed to be measured on the surfaces themselves, and not on the contiguous layer of heat-producing or heat-absorbing substance in contact with the conductor. When the temperature difference is measured as between the heating and heated substances on either side of the plate or layer of conductor, then the conductivity of that conductor not only is very much lower per 1°F. than is specified in the table, but the actual value of the conductivity will be found to depend very largely on the nature and state of motion of the heating and heated substances on either side. Inasmuch, however, as it is useful to know the exact conductivity of the materials themselves, independently of the manner of supplying the heat, the above table has been calculated in its present form; the more complicated considerations involved in the nature and state of motion of the heating and heated substances being dealt with in connection with boilers and furnaces.

Convection is determined by conditions which are not capable of mathematical treatment; the quantity of heat conveyed being dependent upon the rapidity of the heated stream of matter, and this upon whether that stream is forcibly propelled or only permitted to flow naturally. In general, the more rapid the circulation the greater will be the passage of heat.

Table VII.—*B.T.U. radiated per hour from 1 sq. ft. of surface at 1° Fah. temperature above surrounding temperature.*

perature above the temperature of surrounding objects, and into a constant called the coefficient of emissivity of the surface. This product gives the number of units of heat radiated in unit time. According to Péclet, the quantity of heat radiated from incandescent carbon at ordinary furnace temperatures is about equal to half the total heat of combustion. Table VII. gives the number of thermal units of heat radiated from common surfaces under stated conditions.

The relative radiating powers of some important surfaces are given in Table VIII. :—

ELECTRICAL UNITS.

BY ALBERT CAMPBELL, B.A.

Of the three systems of units commonly employed in electrical science, namely, the Electrostatic, the Electromagnetic, and the Practical, the last-named system naturally is by far the most important for the practical man. The electromagnetic system of units comes next in importance, for the practical system is directly obtained from it, the practical units being merely multiples or submultiples of the electromagnetic ones; and, besides, the electromagnetic units are at present used in practical work in some cases where a practical unit has not been chosen and named.

But the electrostatic units have also their domain, and it is one which may in the future become more important: they are the simplest units to use in calculating the capacities of condensers from their dimensions. In electrostatic measurements, too, they are sometimes the easiest to employ, for instance, in working with a Kelvin Absolute Electrometer; but specimens of this noble instrument are exceedingly rare, although text-book descriptions are so familiar.

The elementary text-books, however, are by no means clear enough on the subject of the Electrostatic Units and their connection with the other systems; indeed, most readers get the idea that magnetic pole, strength of field, reluctance, and such like, can only be measured in the electromagnetic system. The object of this Paper is to show the completeness of each system and to indicate definitely the relationships of corresponding units, in particular of those less familiar ones which are not discussed in the ordinary text-books.

Before proceeding to the consideration of the electrical units, it will be necessary briefly to discuss the question of units in general; accordingly, we shall begin from first principles.

In the first place, the amount of anything means the number of times that a certain portion of a similar thing is contained in it; in other words, the quantity of anything is equal to a number × a unit.

Of these two parts, the abstract numerical part presents no serious difficulty, as the properties of ordinary numbers are sufficiently familiar. The consideration of the second part of the expression, namely, the unit, is much more difficult; for the unit is sometimes a concrete thing with many different properties, and it has to be defined and measured by means of one or other of these properties. To take an instance: A unit of heat may be defined in different ways by reference to various properties of heat. Now, heat has the property of changing the state of a body from solid to liquid, and if we select this property we may take as our unit of heat-quantity the amount of heat which will just melt a unit amount of a standard substance, such as ice at its melting point. If we choose the property of producing change of bulk, we shall have, as unit, the amount of heat necessary to produce a certain change of bulk in a given amount of a standard substance under fixed conditions of temperature, pressure, &c. Again, if the property selected be that of producing rise of temperature, we shall have quite a different unit of heat; and similarly for the other properties of heat.

Having thus defined these different units of heat, it is necessary to find the proportions of one of the units to each of the others, and this has to be done experimentally by measuring the same definite quantity of heat in terms of each unit. This means that we have to find the quantitative relations between the various physical properties or effects of heat.

In actual measurements the things ultimately observed are quantities of space and time, and of matter and energy; for example, if we wish to determine the magnetic moment of a given magnet, we observe a mass, a time of swing, and a deflection which practically means two lengths. This way of measurement quite agrees with the results of modern physical science, which tend to show that in the material universe there are two real things, namely, matter and energy, which have been found as yet to be indestructible by physical processes, and which are limited in their action by relations of space and time. But quantities of energy are ultimately determined by their effects in space and time when associated with quantities of matter; accordingly, our fundamental units are of Length, Mass, and Time. And, in order to have a uniform and reasonable system of measurement throughout the scientific world, the particular units which have been chosen by international consent are the Centimetre,* the Gramme,* and the Second.

From the centimetre we derive our units of area and volume. From the centimetre and second we derive the unit of velocity, which is the time-variation of space; and the unit of acceleration, which is the time-variation of velocity. Next, when we have a body (*i.e.*, matter) in motion energy is showing itself; so from unit mass and unit velocity we derive the unit of energy (or work), namely, the erg. [Thus: Two grammes moving with velocity of 1cm. per second has one erg of kinetic energy.] Force being "a mere space variation" of energy, the unit of force is derived from the erg and the centimetre, and is called the dyne. [On this system of derivation, unit force is that which does unit work when its point of application moves through unit distance in the direction of the force.] If we prefer it, we may derive the force unit directly from the units of mass and acceleration.

Last of these dynamical units may be mentioned the unit of Power; since power is the time-variation of energy, *i.e.*, the rate of doing work, its C.G.S. unit is an erg per second.

Proceeding to the electrical units, let us confine our attention in the first place to the electromagnetic and electrostatic systems. Our fundamental units are, as above, the centimetre, gramme, and second; derived from these, we have the erg and the dyne.

To make the notation consistent let capital letters (*for the occasion only*) be used to denote electromagnetic units and small letters for electrostatic units. We may now proceed to build up our two systems of units, each new unit being derived from units already determined, by means of a defining statement (sometimes called a dimensional equation) connecting the new unit with units already known. These defining statements, or formulæ, embody definition and result of experiment, or mathematical deduction therefrom. To make the matter more clear, let us consider a simple case, viz., to derive the current unit from a time unit and a quantity unit, both supposed to be already known. Here the law is that a uniform current of p units flowing for q units of time transfers $p\,q$ units

* The Editor, and not the Author, is responsible for these spellings, as the Author is very strongly of the opinion that the fully Anglicised spellings, *Centimeter* and *Gram*, should be used; and in this he follows the practice of several of our best writers on chemistry.

Digitized by Google

of quantity, ∴ 1 unit of current in 1 unit of time carries 1 unit of quantity; or C in T carries Q.

We may write this shortly thus:—

$$C\,T\,[=]\,Q,$$

and this is the defining statement connecting C with Q and T.

Any other units may be similarly derived as soon as we know the laws and definitions connecting them with their predecessors. In what follows, the defining statements, though not actual equations, will, for shortness, be referred to as formulæ.

Tables I. and II. show the method and order of procedure in each system, the words in the formulæ, as well as the letters (except x, y, v, and π), being taken to denote corresponding units.

Table I.—*Electromagnetic System.*

No.	Formula.	Unit obtained.	
1.	$\frac{M.M.}{(\text{distance})^2}[=]$ force	Magnetic pole,	M
2.	M H [=] force	Magnetic field,	H
3.	$H\,[=]\,\frac{\text{arc}}{(\text{radius})^2}.\,C$	Current,	C
4.	Q [=] C . time	Quantity,	Q
5.	$\frac{Q\,Q}{(\text{distance})^2}[=]\,x\,.$ force	$(x=v^2)$	
6.	M Ω [=] energy	Magneto-motive force,	Ω
7.	4 π F Ω [=] energy	Magnetic flux	F
8.	4 π B Ω area [=] energy	Magnetic induction	B
9.	B [=] μ H	Permeability,	μ
10.	$F\,[=]\,\frac{\Omega}{R}$	Reluctance,	*R*
11.	$2\,L\,C^2$ [=] energy	Co. of induction,	L
12.	Q E [=] energy	Electromotive force,	E
13.	$C\,[=]\,\frac{E}{R}$	Resistance,	R
14.	$K\,[=]\,\frac{Q}{E}$	Capacity,	K

Table II.—*Electrostatic System.*

No.	Formula.	Unit obtained.	
I.	$\frac{q.q}{\text{distance}^2}[=]$ force	Quantity,	q
II.	q [=] c . time	Current,	c
III.	$h\,[=]\,\frac{\text{arc}}{(\text{radius})^2}.\,c$	Magnetic field,	h
IV.	$m\,h$ [=] force	Magnetic pole,	m
V.	$\frac{m\,.\,m}{(\text{distance})^2}[=]\,y\,.$ force	$(y=v^2)$	
VI.	$m\,\omega$ [=] energy	Magneto-motive force,	ω
VII.	$4\,\pi\,f\,\omega$ [=] energy	Magnetic flux,	f
VIII.	$4\,\pi\,b\,\omega$. area [=] energy	Magnetic induction,	b
IX.	$b\,[=]\,\mu'\,h$	Permeability,	μ'
X.	$f\,[=]\,\frac{\omega}{\text{r}}$	Reluctance,	r
XI.	$2\,l\,c^2$ [=] energy	Co. of induction,	l
XII.	$q\,e$ [=] energy	Electromotive force,	e
XIII.	$c\,[=]\,\frac{e}{r}$	Resistance,	r
XIV.	$k\,[=]\,\frac{q}{e}$	Capacity,	k

The above order of deriving the units avoids equations containing differential coefficients, and is probably as simple as any other that can be arranged. It is not necessary to make any remark upon the methods of obtaining the formulæ, except in the case of formulæ (7) and (11). Of these, (7) is derived from (6) by reason of the fact that a unit pole in the electromagnetic system has 4 π unit lines of force proceeding from it. This is a consequence of formula (1). It is *not* the case that in the electrostatic system 4 π unit lines come from unit pole, but it will be found that formula (VII.) is true for all that. Again,

$\frac{1}{2}$ (coefficient of self-induction) × (current)^2 = energy stored; ∴ when unit current C stores unit energy we must have two units of coefficient of self-induction,

i.e., $2\,L\,C^2\,[=]$ energy unit,

which is formula (11).

It will be seen from Tables I. and II. that the two systems differ firstly in the order of deriving the first four units; the electromagnetic proceeding in the order—pole, field, current, quantity; while the electrostatic follows the inverse order, viz., quantity, current, field, pole. The remaining units from magneto-motive force (M.M.F.) onwards may be derived in the same order and from exactly similar formulæ in the two systems.

The second difference lies in the fact that Table I. does not contain a formula $\frac{Q.Q}{(\text{dist})^2}\,[=]$ force unit, nor does Table II. include a formula $\frac{m.m}{(\text{dist})^2}\,[=]$ force unit, for the simple reason that neither of these formulæ is true. Accordingly we find, in formulæ 5 and V., the coefficients x and y, whose values must be found from experiment. It is clear, from formulæ 1—5 and I.—V., that

$$\therefore\ x = \frac{Q}{q} = \frac{m}{M} = \sqrt{y}.$$

Several independent researches (by Maxwell and others) agree in showing that the value of $\frac{Q}{q}$ is approximately $= v$, the velocity of light, *i.e.*, about 3×10^{10} cms. per sec. This result, along with Tables I. and II., gives us immediately the ratio of any electromagnetic, to the corresponding electrostatic, unit. In fact, we have only to compare the corresponding formulæ in Tables I. and II., in the proper order, to get successively the desired ratios as follows:—

$$v = \frac{Q}{q} = \frac{C}{c} = \frac{e}{E} = \sqrt{\frac{r}{R}} = \sqrt{\frac{K}{k}} = \sqrt{\frac{l}{L}}$$
$$= \frac{m}{M} = \frac{H}{h} = \frac{\Omega}{\omega} = \frac{f}{F} = \frac{b}{B} = \sqrt{\frac{\mu'}{\mu}} = \sqrt{\frac{R}{\text{r}}} \quad . \; . \; . \; (15)$$

By the help of these equations we can easily pass from the one system of units into the other. The formulæ in Tables I. and II. also enable us to find the dimensions, with regard to length, mass, and time, of any of the units mentioned (in either system); in other words, the way in which length, mass, and time come in in the measurement of any of the other quantities.

For example, let us investigate the dimensions of permeability in each system. Comparing formulæ (1) and (2) we see that

H × area has same dimensions as M.

Similarly from (6) and (8):

B × area has same dimensions as M.

∴ H and B have same dimensions.

i.e., in the electromagnetic system μ is a mere number.

In the electrostatic system, however, $\mu'[=]\frac{b}{h}$, which has same dimensions as

$$\frac{m}{h \times \text{area}},\ \text{which} = \frac{mh}{h^2 \times \text{area}} = \frac{\text{force}}{h^2 \times \text{area}}.$$

But, from formulæ I., II., and III., h has dimensions $\frac{\sqrt{\text{force}}}{\text{time}}$;

∴ dimensions of (μ' electrostatic) are $[\text{time}]^2 \div [\text{length}]^2$.

If we examine equations (15) it is somewhat surprising that $\frac{H}{h} = \frac{b}{B}$, but careful consideration of formulæ (2), (6), (8) will make the reason clear. It is evident from these formulæ that $4\,\pi$ B × area corresponds with M, while H × length corresponds with Ω. Thus the magnetising force (H) is not to be confounded with the effect (B) which it produces.

Practical System.

To connect either system with the practical system, we have the following:—

1 volt = 10^8 E, and 1 coulomb = 10^{-1} Q;

∴ 1 ampere = 10^{-1} C, 1 farad = 10^{-9} K, 1 henry = 10^9 L,

1 line of flux = F, 1 ampere-turn = 0·4 π Ω.

Digitized by Google

These relations, combined with the last set of equations, (15), give Table III., in which will be found the values of the practical units in terms of the units of the other systems. The joule and watt, although not really electrical units, are also included in the table. 1 supply unit $= 3{\cdot}6 \times 10^6$ joules $= 3{\cdot}6 \times 10^{13}$ ergs.

Table III.

Practical.	Electromagnetic.	Electrostatic.
1 coulomb	10^{-1}	3×10^9
1 ampere..................	10^{-1}	3×10^9
1 volt	10^8	$3^{-1} \times 10^{-2}$
1 ohm.......................	10^9	$3^{-2} \times 10^{-11}$
1 farad	10^{-9}	$3^2 \times 10^{11}$
(1 microfarad...........	10^{-15}	$3^2 \times 10^5$)
1 henry	10^9	$3^{-2} \times 10^{-11}$
(1 ampere-turn).........	$4\pi . 10^{-1}$	$4\pi \times 3 \times 10^9$
	1 line of induction	$3^{-1} \times 10^{-10}$
	1 reluctance unit	$3^2 \times 10^{20}$
1 joule.....................	10^7 ergs	10^7 ergs
1 watt......................	10^7 ergs per sec.	10^7 ergs per sec.

In illustration of the foregoing we shall conclude with the following example :—Express a magnetomotive force of 255 ampere turns in electromagnetic and electrostatic units.

Since 1 ampere turn $= 0{\cdot}4\,\pi\,\Omega$,

$$255 \text{ ampere turns} = 255 \times 0{\cdot}4\,\pi\,\Omega,$$
$$= 320{\cdot}4 \text{ electromagnetic units of M.M.F.}$$

Again, since $\frac{\Omega}{\omega} = v = 3 \times 10^{10}$,

$$\therefore\ 320{\cdot}4\,\Omega = 320{\cdot}4 \times 3 \times 10^{10}\,\omega,$$
$$= 9{\cdot}612 \times 10^{12} \text{ electrostatic units of M.M.F.}$$

In a similar manner we can solve any other problem on change of units.

THE CONDITIONS OF CHEMICAL CHANGE.

In a Paper which he has communicated to the current number of the *Philosophical Magazine*, Mr. V. H. Veley discusses "The Phases and Conditions of Chemical Change." There is much in the Paper which is of interest to electro-chemical students ; for the modern doctrines of ionic dissociation, atomic electric charge, &c., are criticised, and in some instances severely handled. The writer proposes two questions : What is chemical change ? and, What is the cause of its commencement ? To neither of these can the writer be said to give a final answer ; but the views of various authorities are clearly and tersely explained. The tone of the Paper is decidedly sceptical in regard to the modern doctrine that the conditions of chemical change are determined by the presence of ionically dissociated electrolytes. Some rather hard problems are set, in the suggestions of some well-known chemical processes in which it is difficult or impossible to discover any electrolyte. "To take an example from everyday life," says the author, "the materials of a common match-head and box do not apparently contain an electrolyte, yet the chemical change is violent enough when one is rubbed against the other." This is, perhaps, rather begging the question ; quite as much so, for instance, as if the writer should plead his inability to see any electrolyte in dry iodide of nitrogen when it explodes on percussion. Do not the conditions of mechanical friction and percussion correspond in every essential respect with the atomic conditions which are known as ionic dissociation ? The ready chemical change which accompanies the admixture of hydrocarbon oils with bromine, though it is difficult to discover any initial electrolysis here, is a better illustration of the writer's point, and one which he presses with better logic. "In fact," continues Mr. Veley, in his attempt to show that if we acknowledge the doctrine of electrolytic dissociation we must deny the doctrine of energy conservation, "many writers of the present day seem to deal with electric and chemical forces, or electrified and non-electrified atoms, as two cards in a kind of game of blind-hookey, either of which may be turned up at will. . . . . As yet there seems to be no answer forthcoming to the question—Why does chemical change ever begin ?"

THE ACCIDENT AT BOURNEMOUTH.

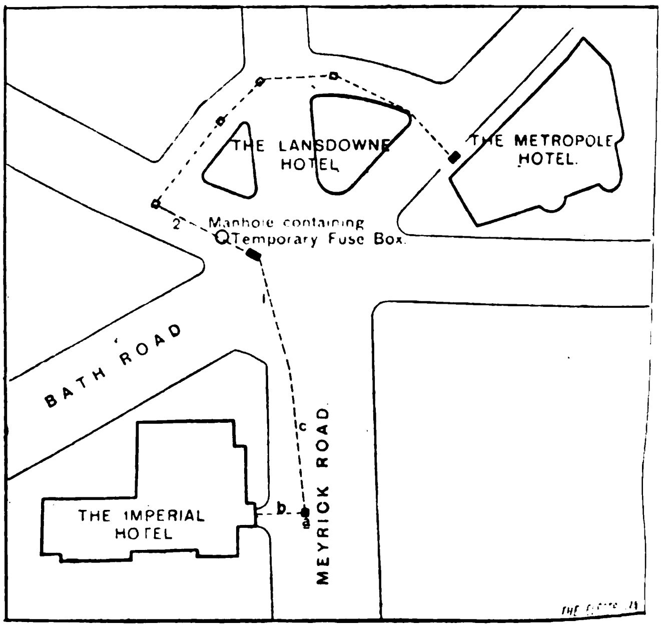
The following report has been made by Major P. Cardew to the Board of Trade on the recent accidental death of a horse at Bournemouth by an electric shock :—

Board of Trade (Railway Department), 8, Richmond-terrace
Whitehall, London, S.W., January 20, 1894.

SIR : I have the honour to report, for the information of the Board of Trade, that in compliance with the instructions contained in your minute of the 8th inst., I have investigated the circumstances connected with the sudden death of a horse at Bournemouth, under conditions which suggested that the cause of death was an electric shock, due to some defect in the mains of the Electric Lighting Company. The following account of what took place I have collected from the narratives of eye-witnesses.

Between half-past two and three p.m., on the afternoon of the 8th instant, a station omnibus drew up in the roadway opposite to the entrance to the Imperial Hotel in Meyrick-road, Bournemouth. As the horses drew up both suddenly fell down. The driver, William Dean, states that he is certain that the horses did not slip, although there was some melting ice and snow on the road at the time. The driver got down to attend to the horses and he was assisted by the following men : John King, flydriver ; W. Brown, flydriver ; T. Binden, carpenter.

All these men, as well as the driver, state positively that when they touched the horses they experienced tingling sensations in their arms and legs, which they attributed to slight electric shock. None of them, however, appear to have been injured by the shock, but the driver's foot was hurt by one of the horses treading on it. One horse was extricated and set on his legs, which appeared to be partially paralysed at the time ; the other could not rise, and died in a few minutes.



Plan showing Service to Imperial Hotel, Lansdowne Crescent, and Metropole Hotel.

On arrival at the spot about noon on the following day, accompanied by the Borough Engineer and the Superintending Engineer of the Bournemouth and District Electric Supply Company (Limited), I had the ground opened at the place where the horses fell, and the iron cover of a street box, measuring 2ft. 6in. by 1ft. 6in., was disclosed about 9in. beneath the surface of the road. On lifting this cover it was found to rest on a brick chamber about 1ft. deep, to one end of which was connected a 3in. iron pipe, and to one side a 1½in. iron pipe. The larger iron pipe contained two insulated cables, technically described as 7/20 tinned copper wires insulated with high quality vulcanised rubber to $\frac{1}{16}$th inch thickness, and protected by braided hemp. The ends of these cables projected to about the centre of the box, and were sealed up with india-rubber tape and composition. Near these ends two smaller cables of 7/21 tinned copper wires, insulated with similar material but only to barely $\frac{1}{25}$th inch in thickness, and with braided hemp outside, were joined to the larger ones and passed into the smaller pipe. The larger cables had been connected to the supply mains through fuses, contained in a large subterranean chamber, at the crossing of main roads known as "The Lansdowne," about 70 yards away. This connection had, however, before my visit been severed by cutting the cables in the chamber. The smaller cables merely completed the connection to the transformers placed in the area of the hotel, and were 34ft. in length, and the enclosing pipe was laid at a depth of about 18in. below the surface throughout. All the cables mentioned were used for the high-pressure supply of 2,000 volts.

There were no signs of any arcing or injury to the cables or to the lid of the street box, the under surface of which was 5½in. above the cables, but I noticed that one of the "dead ends" beyond the joint to the small cable was covered on the outside with a slimy moisture, and I had this end cut

Digitized by Google

off for further test. On testing it subsequently in water with 2,000 volts alternating pressure, however, no fault was developed.

In order to thoroughly examine the cables and the street box it was necessary to move the former slightly, but they were disturbed as little as possible, and a test was then made of the insulation of both larger and smaller cables together, up to the point where the connection to the mains had been severed at the large chamber. This test made with about 100 volts from a small hand machine gave an insulation resistance of between 4 and 5 megohms from the small pipe—a result which did not indicate any serious leak, considering that the cut ends of the cables had not been sealed up, and some leakage from them was to be expected.

On consideration of the matter, however, it occurred to me that possibly the slight movement to which the cables had been subjected had sufficed to move a small defect in the insulation away from contact with the pipe, or that the fault might be such as to give high insulation with 100 volts, but to break down when the pressure was increased to 2,000 volts, so that the fault would not be discovered by the electric test I had made. I therefore requested the Electric Light Company to send for my examination the whole of the cables mentioned so soon as they had withdrawn them from the pipes. This was done, and a distinct defect of insulation was discovered in one of the smaller cables, with evident signs of sparking and some burning of the insulating material having taken place. I do not think, however, from the appearances, that the whole leakage current could have much exceeded one ampere.

Judging from the results of my investigation, and from the attached copy of the report of the borough veterinary surgeon of the *post-mortem* examination made on the horse, I have no doubt that the latter did receive an electric shock, and that probably this shock was the determining cause of death, but that, nevertheless, the shock could not have been a very severe one, and I am inclined to attach much weight to the veterinary surgeon's expression of opinion that the dilatation of the heart may have been a predisposing cause of death.

In order to further elucidate the above, I attach a rough tracing of the locality in which I have marked the street box (*a*), the small pipe (*b*), and the larger pipe (*c*).

My explanation of the occurrence is as follows:—In the first place, the soil at Bournemouth is of such a nature that it is very difficult to get what is technically known as "good earth." There are alternate layers of sand and clay, and either of these may, under certain conditions, oppose great resistance to the passage of electricity. The soil in which the street box (*a*) and the pipe (*b*) were placed was a peaty sand, but probably a layer of clay exists at no great distance below. Secondly, the accident happened during the progress of a thaw after a very severe frost. Now water in the solid form is not nearly so good a conductor as it is when liquid, and the juxtaposition of masses of thawed and masses of frozen ground may have greatly influenced the direction and amount of current flow. It is just possible that the small amount of heat produced by the current in the wires contained in the pipe may have determined a more complete thawing of the ground directly above the pipe than in other parts. Thirdly, the pipe which appears to have been directly charged from the cable was only 24ft. long and 1½in. in external diameter, and was not metallically connected to the larger pipe, but terminated at the brick-work of the street box. Even in soil of a highly conducting nature it would, I consider, be possible to appreciably charge such a short length of pipe by contact with a high-pressure electric wire. Owing to the special conditions above referred to, the potential of the surface of the ground immediately above the pipe appears to have been appreciably affected, and the horse seems to have placed its hind feet upon this charged surface. At the same time one fore foot would be four or five feet distant and very probably in contact with more freely conducting soil. A current from the charged to the uncharged, or at any rate less highly charged ground, therefore, passed through the body of the horse.

That any such result as the death of a horse should have followed from so indirect and limited an application of electricity is indeed an extraordinary occurrence, but while the field of inquiry it opens to view must be carefully studied, and any additional precautions which may after due consideration be thought necessary firmly insisted upon by the Board of Trade, I do not think there was any appreciable danger to human life in this case. Experience in many countries has shown that horses are peculiarly susceptible to electric shock, and a horse necessarily, even when at rest, is in contact with the earth at points much farther apart than are simultaneously touched by men, while the iron shoes and nails of the former and its greater weight ensure a more perfect contact where it does touch. These differences are well brought out by the testimony of the men who extricated the horses. When they touched the bridles they felt a shock, because their feet were resting on the ground about 7ft away from the hind feet of the horses; but not one of them appears to have been conscious of any shock at all, except from contact with the horses.

The suggestion that people inside the omnibus might have been injured by an electric shock is quite untenable. It is, of course, needless to point out, however, that many people's lives may be jeopardised from the result of an electric shock given to a horse, and that on this account alone it is essential that all danger of such an occurrence should be avoided.

I cannot acquit the Electric Lighting Company of blame in the matter. They had warning by their own tests that a defect of insulation existed on this circuit, but they had taken no steps to localise and remove it, although the insulation of the circuit was considerably below 1 megohm. Also on the very day of the accident, as will be seen from the attached copy of a report from one of the foremen in the employ of the Corporation, they had received a warning of the state of things, which they should at once have attended to.

I must also point out that in my opinion the use of such small and thinly-insulated wires carrying high-pressure currents for electric lighting is most injudicious. The cable which failed on this occasion is apparently exactly similar to that which caused the death of a line man on the House to House Company's system rather over a year ago, and other companies have, I am informed, experienced trouble with cables of this size and description.

In order to prevent any recurrence of similar accidents the Company should, in my opinion, take the following steps:—(1) Immediately replace all cables used for high pressure similar to that which caused the accident by larger cables having a thickness of insulation of not less than one-tenth of an inch of best quality india-rubber or some equally-efficient material; (2) connect together all the pipes in which high-pressure cables are contained, and wrap the cables where they pass through street boxes with a sufficient covering of sheet lead, or encase them in iron cases also connected with the pipes, so that the cables should be enclosed throughout in metal casing in connection with earth over the full extent of the system; (3) submit to the Board of Trade for approval, as required by Regulation 10, some efficient pattern of leakage indicator; (4) take immediate steps to localise and remove any defect of insulation which may occur on their circuits.

The Assistant Secretary, Railway Department, Board of Trade.

I have, &c., (Signed) P. CARDEW, Major, R.E.

Report of the Veterinary Surgeon.

Bournemouth, January 9, 1894.

SIR: I beg to report that, acting on your instructions, I have in conjunction with Mr. Goodall, F.R.C.V.S., of Christchurch, and Mr. Blake, M.R.C.V.S., of Bournemouth, made a *post-mortem* examination of a grey mare, the property of Mr. Melton, which was reported as having died suddenly, January 8th. We found a bruise extending along the right side of the body from about the seventh to the twelfth rib. There was an ecchymosed spot on the corresponding side of the pleura. There was marked hyperaemia of the muscles of the anterior part of the body, the muscles of the posterior part were analmic. The abdominal organs were healthy. The spleen was slightly enlarged, the substance was examined by the microscope and was found to be healthy. The lungs were congested. There was dilatation of the right ventricle of the heart, the valves were normal. The blood was fluid and black in colour. The brain was healthy. Rigor mortis was present. I am of opinion that the *post-mortem* appearances were consistent with death being caused by an electric shock. I am further of opinion that the dilatation of the heart may have been a predisposing cause of the death of the mare.

I am, &c.,

John Druitt, Esq., jun., Town Clerk.

(Signed) J. T. KING, M.R.C.V.S., Borough Veterinary Surgeon.

Report of the Foreman.

January 8, 1894.

SIR: Carter J. Hooper reports that he went to the Imperial to collect ashes about 7:30 a.m. this morning. When he arrived there his horse became startled as if by shock, and he says that he himself felt the shock of electricity in his legs, also in his arms. J. Scott, assistant ash carter, that was with him, reported as above mentioned to me. I at once sent him to the offices of the Electric Light Company in the Albert-road to report the same which he done (viz.) to some young person that was in charge of the offices at the time.

Mr. Turner.

(Signed) W. ELCOCK, Foreman.

TELEGRAPHIC COMMUNICATION BETWEEN ENGLAND AND INDIA, ITS PRESENT CONDITION AND FUTURE DEVELOPMENT.*

BY E. O. WALKER, C.I.E.

(Concluded from page 389.)

When communication between England and India was first opened, the unit of charge was a message of 20 words for £5, or at the rate of 5s. per word. In 1876 the minimum chargeable unit was reduced from ten words to one word, containing not more than ten letters, but the charge was fixed at 4s. 7d. This was a distinct improvement. In 1887, the charge was 4s. 2d. per word, and at the present time from England to India the rate is 4s. *via* Suez and Teheran, and 3s. 8d. *via* Turkey. The charges in India are altered from time to time by the Government, to prevent loss by exchange, since payment must be made to the companies in gold, a proceeding which is unwelcome to the commercial community, and which, when applied in South America, was resented, and had to be abandoned.

As regards the revenue afforded by messages in the early days of the overland telegraph, I have not complete figures. But, in 1868, the Indo-European Department and the Turkish line earned something like £187,200. The opening of the Suez route at once diverted a large portion of the traffic, and it also stimulated it. The Eastern Telegraph Company has never paid less than 5 per cent., and often more than 6 per cent. The Indo-European Company, although for a few years unremunerative, was able to pay 5 per cent. in 1874, has not paid less than 8 per cent. since 1880, and as much as 12 per cent., and in the past five years often 10 per cent. The returns for the Turkish lines are not available, but a small percentage only of the overland traffic between Europe and the East now passes over them. In 1891-92, 92·4 per cent. went *via*

* Abstract of a Paper read Thursday, February 8th, before the Indian Section of the Society of Arts.

Digitized by Google

Teheran, and 7·6 per cent. *via* Turkey; but this is fully accounted for by the fact that the mean rate of transmission in that year by the former route was one hour, and by the latter sixteen hours. It may be remarked in this contrast that the Indo-European Department, controlling the lines from Kurachi to Teheran, has been of late years only able to show a credit balance. In 1891-92, the net profit was 1·4 per cent. This is due to the heavy outlay on the Persian Gulf cable, and this, gentlemen, is an important factor in determining the telegraphic rate to India. In 1878 an agreement was effected between the Eastern and the Indo-European Companies and the Indian Government for a "joint purse," based on the actual traffics each line dealt with. By this arrangement the Eastern Company gets 60·39 per cent. of the revenue for Indian traffic, and the other Company, with the Indo-European Department, 39·61 per cent.; for trans-Indian, or Far East traffic, the figures are 80·53 and 19·47 per cent. respectively. The actual percentages of traffic since carried differ from these figures. The averages, from 1878 to 1892, for Indian messages, are 56·5 per cent. *via* Suez, and 43·5 *via* Teheran. Although the Cable Company may have had a larger share of the earnings than the actual work done would justify, still it must not be overlooked that the support it has afforded to the overland lines in times of interruption has been immense, and the co-existence of the two routes (leaving the Turkish aside as being comparatively unpopular) has proved to be indispensable in retaining and in fostering the traffic.

The amounts earned and paid into the "joint purse," on account of Indo-European messages for some of the years, from 1878 to 1892, are given below:—

1878-79	£310,009
1881-82	360,011
1888-89	335,257
1891-92	360,098

1891-92, the share of the Eastern Telegraph Company was £217,465; of the Indo-European Company, £80,445; and of the Indo-European Department, £62,188. If the overland lines had retained all they earned in that year, their shares would have been £106,488 and £81,760 respectively. All administrations concerned earned something more for Far East traffic, with the Straits Settlements, China, Australia, New Zealand, &c., the share of the Eastern Telegraph Company on this account being £229,045, of the Indo-European Company £34,218, and of the Indo-European Department £21,164. The dividends paid by the first two were at the rate of 6½ and 10 per cent. respectively.

The capital, including Ordinary, Preference, and Debenture stock of the Eastern Telegraph Company was, in 1891-92, £6,100,000, and its reserve fund £442,014. The capital of the Indo-European Telegraph Company remained at £425,000 and its reserve was £172,839. These last figures, coupled with those of the excellent dividends distributed, and also the admirable service afforded by the Company, will show what land lines can do when well administered. The capital expenditure by the Indo-European Department, up to the year under review, was Rx.1,150,000.

The figures given above include the revenue derived from Continental messages as well as those of the United Kingdom. Supposing the number of telegrams to be proportional to the whole value of the trade, then, in 1892, one quarter would have been sent between India and the Continent and three-quarters to or from the United Kingdom. Thus out of the revenue for 1891-92 for Indian traffic, £270,000 was approximately contributed by Anglo-Indian and £90,000 by Indo-Continental messages. I would ask attention to these figures, since they are material to the subsequent argument.

Now, I have little doubt that it will surprise most to know that the total amount paid for telegrams between India and the United Kingdom in 1891-92, namely, £270,000, was only about a quarter per cent. of the value of the total trade, Rx.95,222,155. I attribute this unnatural restriction of traffic solely to the high rate which prevails. Small traders cannot, on account of the expense, use the wires, and I think my friends in India will bear me out in the statement that foreign telegrams are, as a matter of fact, sent by the comparatively few wealthy firms. Private persons, owing to the cost, rarely communicate between England and India by telegraph. Now, the last twenty years have witnessed an extraordinary extension of inland telegraphs in both countries. Speaking from experience in India, I can say that they have largely aided in the transport of produce, and in bringing up-country merchants into connection with distant markets, with which formerly communication was difficult and slow. In order to make a profit at the present day it is often necessary that transactions should be effected quickly, and whenever telegrams are made cheap it has been found that they are readily used for this purpose. Moreover, native firms are learning to deal direct with European manufacturers. Could they communicate by telegraph, at a low charge, there can be no doubt that the trades concerned would receive a stimulus. It is, perhaps, open to doubt, whether it would be a public benefit to afford cheaper means than exist at present, by which the Secretary of State could speak to the Viceroy of India. There would, however, be a large reduction in the present considerable telegraph bills of the two Governments, and they should be, equally with the general public, interested in lowering foreign telegraph rates. Setting the Continental traffic aside, India and England only exchange about 465 messages per working day. This fact, when compared with the volume of their mutual trade, and with the enormous political interests common to both countries, speaks for itself.

Now, with effect from May 1, 1891, some of the Australian colonies entered into an agreement with the telegraph companies to make up half the loss, if such loss should occur, on a reduction of charge from 8s. to 4s. per word between England and Australia. The difference was a large one, and experience has shown that a certain loss has been incurred, but that if the reduction had been spread over ten years instead of being wholly effected at once, there would have been no loss. Probably in a shorter time than that the increase of traffic would have paid for the reduction. From January 1, 1893, the rate was raised to 4s. 9d., at which it is anticipated there will not be a deficit in the revenue. I believe the situation is one in which the Home and Indian Governments might, in their own and in the public interest, exert themselves. Apart from the cheapening of communication by extending the overland lines, a course which is quite practicable, I hold that the Companies are in a position to gradually lower the rate, and that experience proves that, done cautiously, the greater facilities thus afforded will prevent loss of revenue.

The question next arises, What amount of traffic could be easily carried by the Indo-European and Eastern Companies with their existing lines should the introduction of a reduced rate largely augment the number of telegrams? I will suppose that two out of the three cables are used for through traffic to India, and that there are two through wires *via* Teheran. These four working circuits are capable of carrying at least each fifteen words per minute, or, say, to give you a better idea of their capacity, one message per minute. In 24 hours a traffic of 5,760 messages could be dealt with, or five times what passes at present between Europe and the East. But there is another feature in modern telegraphy by which, without increasing the capital outlay by more than a small sum—£15,000 in the case of the Eastern Company's cables—the carrying capacity of the circuits is almost doubled. This is the "duplex system," which by special arrangements of apparatus at the ends of a circuit, but involving no alteration of the wire or cable itself, permits of messages being transmitted simultaneously from each end. Dr. Muirhead's efficient duplex system, which was applied to the Eastern Company's cables some twelve years ago, about doubles the carrying power of a circuit, I am informed, and thus the Company is in a position to carry a very large traffic without going to the expense of laying extra cables for it. Many men will think that the public might have been allowed to participate in the advantages accruing from this new method by the concession of lower charges. Anyhow, it affords means of now dealing, in conjunction with the Indo-European Company, with over 7,000 messages daily. The lines of the latter are not, I believe, at present using the duplex system, but there is no difficulty in applying it, and increasing largely the ability of the Company to cope with a large traffic. Then the Turkish route, in capable hands, can be made as serviceable as the others. It is quite possible that, owing to telegrams on business being despatched during working hours, that the bulk of the traffic will be confined to part of the day only, and, at the same time, desirable that it should not be allowed to accumulate. Supposing even that it is dealt with between 11 a.m., London time (*i.e.*, 4 p.m., Indian time), and midnight. Then the present circuits duplexed could carry over 4,000 messages in that interval, with no excessive delay on each. Were all these Anglo-Indian messages at a rate of two rupees, or two shillings and sixpence per word, they would produce a revenue of £6,850 per day, taking each message to consist of 13·7 words, as was the average for private messages in 1891-92, or over £2,000,000 for the year of 300 working days, which, after deducting the Indian Government share, would leave something like £1,750,000 to be divided between the companies, against £650,000 at present. Of course, I am aware that even at a rate of 2s. 6d., the traffic is not likely to increase with so great a bound, but there is little reason to doubt that with India, as well as the Far East, it will be worked up to in twenty years, if charges are subtantially lowered at intervals in that period.

With a growing foreign trade, the revenue in 1891-92, from Indo-European traffic, was about the same as that for 1881-82—about £360,000. Some will attribute this to the process of condensation, or codification, which has been going on—that is, the use of letter or word cipher. No doubt this has unfavourably affected revenues, but then it is a science fostered by high tariffs. I am prone to think that the want of progress is rather due to the fact that there has been practically little reduction in cost per word for twenty years. I venture to assert that, in existing circumstances, looking at the dividends paid, the substantial reserves accumulated, the reduced cost of cables, as

Digitized by Google

compared with twenty years ago, and at the fact that the lines can carry a much larger traffic than they do, the public has a claim, and the companies and the Governments of India and this country have an interest in making Anglo-Indian telegrams cheaper. I would add that the Indian public ought to be relieved of fluctuating charges for the messages, made to depend upon the course of exchange. The charge can, and should be reduced by 6d. yearly, until the present rate—4s.—is lowered to 2s. 6d. This course would obviate any serious falling off in receipts. No guarantee by Government, nor by the commercial communities concerned, should be required to insure the companies against loss in taking this step. Their present position is sufficiently strong financially to admit of their incurring the risk.

But, in my opinion, what is essential to the introduction of a permanently low charge is the extension of the overland systems of telegraphs. I desire to point out that there are three links to be completed in these systems, which would, with a properly organised service under central control, in connection with the European lines, certainly afford means to India and England of exchanging correspondence far more cheaply than at present. They are as follows:—Shiraz to Jask, in Persia, 575 miles, a telegraph line by this route will, at a cost of £35,000, complete the overhead wire from London to Calcutta, with the exception of the short cable across the channel. This amount is less than the cost of maintenance of the Persian Gulf cables for two years. A new trunk line from England to India, *via* the Continent, Russia, and Persia, with the necessary offices, would not, in the light of the experience we now have, and at the present chief prices of materials, cost more than £450,000. The Home and Indian Governments might possibly find it economical to construct such a line, primarily for their own correspondence. I would remind you that there are two wires by land already—from Kurachi to Jask, and from Shiraz to Teheran. The period of the Indo-European Company's concession from Prussia, Russia, and Persia, and the convention existing between India and Persia, will expire in 1895, and a favourable opportunity thus occurs of revising arrangements with regard to overland communication with India.

The second link, which it is important to complete, is that from Mashad to Herat, and thence to Kandahar and Quetta. From Teheran to Mashad, 562 miles, there is now a telegraph line belonging to the Persian Government, but maintained by the Indo-European Department. Mashad sent about 2,000 messages to the Persian Gulf stations in the year 1891-92, a fact which shows that when these out-of-the-way places are connected by telegraph with trade outlets, the local traffic is an important item in estimating revenue. From Mashad to Herat is about 240 miles. From Herat to Quetta, *via* Kandahar, some 500 miles, there are no physical difficulties; and there is every likelihood that, before long, the present Amir will look favourably upon the introduction of the telegraph, equally with other applications of modern science, into his dominions. At Quetta, the lines of the Indian Telegraph Department are connected with the Punjab and with Kurachi. I shall be told that the telegraph work in Afghanistan is perilous. No doubt at first it will be. The telegraph operations in Burmah have been difficult and hazardous, but most of the lines are now permanent and reliable. In the Afghan war, Mr. Luke, of the Indian telegraph, managed to keep the wire open from Kabul to Peshawur, and Mr. Pitman, at Kandahar, held communication with Kurachi. The difficulties now to be encountered, with a Government favourable to the enterprise, would be comparatively light.

There remains one more important gap to be filled up in the Asiatic systems of telegraphs, namely, that from Merv to Herat *via* Penjdeh. These are joined by a road about 240 miles in length along the valley of the Murghab. A telegraph line here will, when Herat is connected to Quetta, unite India with the present Russian Asiatic telegraphs that lead to Europe by the Caspian Sea. A second trunk line through European Russia, *via* Merv and Herat, and so to India, will afford a valuable alternative route in time of peace, and by this, in combination with the line of the Indo-European Company, or another through the south of Russia and Persia, the whole of the traffic between Europe and the East could be carried. Such lines would probably earn much from local traffic. The cost, not more than a million sterling, for the two separate lines, would admit of messages passing between England and India at a shilling per word, with provision yet for interest, at the rate of 8 per cent. on the capital.

It is essential to the success of the working of long lines passing through foreign territories that they should be administered by one responsible directorate, and existing circumstances point to the Home and Indian Governments, as well as the Company that has already achieved such good results, as the authorities best qualified to promote telegraphic enterprise in the localities I have indicated. No time should be lost in acquiring the rights to do so. By diplomacy and the timely grant of small subsidies, the exclusive appropriation by these routes of certain wires for an international service could be secured.

THE ST. PANCRAS ELECTRIC LIGHTING INSTALLATION.*

BY PROFESSOR HENRY ROBINSON, M. INST. C.E., M. INST. E.E.

I have pleasure in complying with the request that I should describe at the Society of Arts the Electric Lighting Installation that I have carried out for the St. Pancras Vestry. I would state at the outset that St. Pancras was the first municipal authority to appreciate the importance of preserving the business of electricity supply in its own hands.

On the passing of the Electric Lighting Act, 1882, I, in conjunction with Dr. Hopkinson, F.R.S., advised the Vestry to obtain a Provisional Order, and it was obtained in 1883. Owing chiefly to financial and other difficulties in connection with the Electric Lighting Companies, as before mentioned, public confidence was shaken, and the Order remained in abeyance. In 1888 various companies made applications for Provisional Orders by which the metropolis was proposed to be divided amongst them, but at the Board of Trade enquiry that was held in 1889, the St. Pancras Vestry succeeded in getting their district excluded from the operation of any company. I was thereupon instructed to prepare a scheme to serve, in the first instance, the south-west, or Regent's-Park, division of the district, which formed the compulsory area under the Order. In advising upon this, I kept in view the ultimate requirements of the other parts of the St. Pancras district, so that the first installation should form part of a comprehensive scheme. I decided upon adopting the continuous-current system.

The situation of the site that was originally proposed by the Vestry necessitated the employment of high tension, with five transformer sub-stations to feed a network of low-tension distributing mains. The ultimate acquisition by the Vestry of a more central site in Stanhope-street (consisting of 21,000 square feet of freehold property, purchased for £10,000) enabled me to adopt the low-tension direct supply system entirely for private lighting, and to have only one battery sub-station at the Cobden Statue, 1,140 yards from the central station. It was decided to work the public arc lamps by high-tension continuous-current independently of the private lamps. The plant was designed at the outset to serve 10,000 incandescent lamps of 16 c.p. simultaneously in use, and 90 arc lamps of 10 amperes each for public lighting.

I should mention that the action taken by the Vestry was not adopted without strong opposition being offered (which is, in fact, still continued) to the Vestry's undertaking this work. However, on January 1, 1890, authority was given by a large majority for the work to proceed. Having overcome opposition from within, a quite unexpected difficulty arose in consequence of uninvited advice and proposals being made from outside (not altogether of a disinterested character) which disturbed the minds of the Vestry.

On my advice, Dr. Hopkinson and Mr. Preece were consulted, and it was a satisfaction to me that they entirely concurred in my proposals, and the execution of the works, which had thus been interrupted, was proceeded with.

The following is a description of the works:—The buildings consist of an engine-house 106ft. by 26ft., a boiler-house 53ft. by 35ft., coal store 43ft. by 11ft., battery-room 40ft. by 14ft. 6in., testing-room, office, stores, underground tank for condenser water, containing 170,000 gallons, chimney 5ft. square inside and 90ft. high.

There are eleven engines and dynamos, which are erected on a concrete foundation surrounded by sand to prevent vibration being communicated to the walls, and the floor is carried, independently of the engine foundation, by cantilevers from the walls. The engines are of the Willans type, and the dynamos are of the six-pole Kapp type (made by Messrs. Johnson and Phillips). Nine of these are wound for an output of 680 amperes at pressure varying from 112 to 130 volts. Three are capable of giving 145 volts with a small current for charging batteries at the sub-station, and can be worked self-exciting as simple shunt machines, or separately excited. They were tested with a load of 680 amperes at 118 volts, and the steam consumption was found to be 18·65lb. per electrical horse-power per hour, working condensing, and with the dynamo separately excited. The remaining two dynamos are wound for an output of 90 amperes at from 540 to 575 volts. They are separately excited at low tension, and are used for working 86 arc lamps in the streets, as well as for charging in series four sets of storage batteries of 60 cells each at the central station, which are capable of discharging 60 to 75 amperes. The trials of these two engines showed a consumption of 19·6lb. of steam per electrical horse-power per hour.

There are five Babcock and Wilcox boilers, each being 23ft. long and 5ft. wide between the walls, with one steam drum 3ft. 6in. in diameter. Each boiler has a heating surface of 1,619 sq. ft., and a grate area of 30 sq. ft., and is capable of evaporating over 5,000lb. of water per hour, the working pressure being 170lb. per square inch.

* Abstract of a paper read before the Society of Arts on Wednesday.

Digitized by Google

There are two 6in. steam mains along the top of the boilers fed by separate outlets from each boiler, and delivering into a 6in. main (which extends the whole length of the engine-house) at three points. The mains are so arranged that only two engines are put out of use by the removal of any one pipe. The long pipes are made of wrought-iron, the short pipes and T-pieces of cast-iron, and the bends of copper. The main exhaust-pipe, under the engine-house floor, varies from 5 to 15in. in diameter. The steam can be exhausted to the atmosphere, but under ordinary circumstances it passes into a jet condenser, which draws its water from the bottom of the underground tank. Two air pumps, driven by a Willans's compound engine, discharge the hot water from the condenser into the top of the tank. A Körting ejector condenser is provided as a stand-by for heavy loads. From the top of the tank the hot water is pumped by independent circulating pumps to a cooling apparatus, which is capable of dealing with a minimum of 10,000 gallons per hour. The cooling arrangements consist of a large surface of corrugated iron sheets, attached to framing placed round the chimney shaft, the water, after flowing over the corrugated surface, being collected beneath and returned to the bottom of the tank.

A dry-air machine is provided for the purpose of delivering dry air into the street main culverts at the rate of 5,000 cubic feet of air per hour. The air has its dew-point lowered to 40°F.

The arc lamp-posts (86 in number, displacing 479 gas-lamps) are of the Brockie-Pell type, and are placed in the centre of the road, where this is admissible. In some places, however, they had to be placed on the pavements, as tramways prevented them from being in the middle of the roads. The first lamps that were erected (in Tottenham Court-road and Euston-road) are 25ft. from the ground to the centre of the globe, but those more recently put up, which are chiefly on the pavements, are 22ft. They are fixed at distances varying from 160ft. to 245ft. apart, and are fed with a current of 10 amperes. Eleven lamps are worked in series near the central station, and ten in series at a distance. Nine arc lamps have more recently been put up in Park-street and supplied with current off the low-tension mains.

The main switchboard is arranged on the three wire system. Each dynamo is provided with a double pole switch and copper coupling straps to connect the machine to the third wire and to different bars on the feeder-board on either side of the circuit. There is an ampere meter on each dynamo. One terminal of the dynamo switch is coupled by a strap to the third wire main, and the other terminal is coupled to a bar on the feeder-board. There are four positive bars and four negative bars, and at full load one machine can be run on to each bar and worked at any pressure which may be necessary to serve the feeders which are switched on to it. Thus the dynamos may all be worked at different pressures to suit the demand in the districts which they serve. There are seven feeders, in addition to a direct supply on to the distributing mains, which are connected in a network throughout the district. The bars on the board may be connected directly in parallel or through resistance cells, which will each carry currents up to 180 amperes, offering a counter electromotive force of from 2 to 2¾ volts. By using these cells current can be supplied to the feeders at four or five different pressures from one dynamo, which enables the dynamos connected to long feeders to help those serving short feeders, and further enables regulation over large areas when only one dynamo is at work on each side of the circuit.

There is an underground sub-station beneath the open space at the Cobden Statue, High-street, Camden Town, at a distance of 1,140 yards from the central station, which contains two batteries of 58 cells each.

The mains are laid throughout on the "three-wire-system," the arterial mains being sufficient to supply 25,000 lamps of 16 c.p. in use simultaneously. The conductors are chiefly composed of bare copper strips 1½ in. wide and ⅛ in. thick, supported on edge in glazed porcelain insulators, which are carried on small cast-iron brackets built into the walls of the culverts. Some of the mains are cables laid in cast-iron pipes, and in the extensions now being carried out they are Siemens armoured cables.

The works originally authorised, I estimated would cost about £50,000, and this estimate was increased to abcut £52,000 when the Stanhope-street site was adopted. The actual cost of the works when completed was about £56,000, or within 8 per cent. of the estimate, which, I think it will be admitted, was satisfactory. During the execution of the works originally authorised by the Vestry, extensions were made by the Vestry which involved a considerable increase in the capital expenditure.

The works were so far completed as to enable public supply to be commenced on November 9, 1891 (or a year after laying the first stone). By the end of January, 1892, there were 6,500 incandescent lamps of 16 c.p. installed (or their equivalent), and at the end of 1892 there were 11,733, and at the end of 1893, there were 14,617 lamps installed, and many more contracted for, to come on shortly.

The current for ordinary supply is charged at 6d. per unit, but it is charged at only 3d. per unit for what is termed "day load," but which might be defined as current supplied for motive-power and other purposes at times other than those of maximum demand.

The public lighting is at present charged for at the rate of 6d. per unit, which covers the entire cost of production as well as for carbons, trimming, &c., together with all capital charges and maintenance, including lamp columns, lamps, street refuges, &c. The electricity department takes charge of all these matters, and the public lighting account is only debited with one item, "current used," at 6d. per unit. The cost of carbons and trimmings for the 95 public arc lights in 1893 was about £600.

Capital Expenditure to December 31, 1892.

Lands (part only utilised)	£10,027	0	0
Buildings	7.653	17	1
Machinery and plant	24,378	17	8
Batteries at central station and sub-station at Cobden statue	2,961	6	11
Mains, of which some are capable of carrying current for 25,000 lamps	33,787	15	3
Public lamps	6,723	8	4
Meters	1,556	3	9
Electrical instruments, &c.	284	16	3
Office, and other furniture, and fittings	186	7	4
Preliminary expenses	554	4	7
Total expenditure to December 31, 1892	£88,913	17	2

During the year 1893 a sum of about £10,000 was expended in extensions of public lighting, together with mains, meters, house connections, &c. A further increase of the generating plant at the central station has been rendered necessary, owing to the increasing demand for current. These works are now nearly completed, and consist of an extension of the central station buildings to receive three more engines and dynamos, three additional boilers, together with a second sub-station in Fitzroy-road, near Primrose-hill, 2,700 yards from the central station, containing two sets of batteries. These extensions will cost about £13,000.

The "fixed charges" in the shape of the permanent staff, &c., commenced in the middle of 1891, before the public supply of current began. Some of the working expenses of the Station during that year, and also in 1892, were incidental to a new undertaking. The following figures for those years, therefore, do not admit of being taken as any criterion of what the normal relation between receipts and expenses will be, but they are given as a matter of record. From the commencement of public supply in November, 1891, to the 31st of December, 1892, there were 11,733 lamps of 16 c.p., or their equivalent current, installed (including 11 motors = 36 H.P., and 92 private arc lamps), of which 6,823 were in simultaneous use. The number of units sold to the end of 1892 was 433,519. The amount charged for lighting the 86 public arc lamps (which were at work only part of the year) was £2,040, the current being charged at 6d. per unit. The total working expenses of all kinds from the commencement to the end of 1892 were £7,438. A sum of £408 was expended on the maintenance of plant. A capital sum of £4,119 was repaid, made up of £400 capital and £3,719 for interest on loans at 3½ per cent. The number of tons of coal used to the end of 1892 was 2,728, and its cost was £2,828, the price of coal being from 20s. to 21s. 6d. per ton.

For the year 1893 the following are the figures :—

Number of 16-c.p. lamps, installed, or equivalent current, including 19 motors = 61 H.P. and 110 private arcs		14,617
Number of 16-c.p. lamps, or equivalent current, simultaneously in use		6,187
Number of units sold for private lighting		397,217
Number of units sold for public lighting		197,676
Total number of units sold		594,893
Receipts for private lighting		£9,546
Receipts for 93 public arc lamps, the current being charged at 6d. per unit		£4,941
Total receipts for current		£14,487
Working expenses		£7,033
Repayment of capital	£1,628	£4,425
Interest on capital, at 3½ per cent.	£2,797	
Expended on maintenance		£1,402
Total for working expenses, repayment of capital, and maintenance		£12,860
Number of tons of coal used		3,180
Cost of coal (price about 17s. 9d. per ton)		£3,003
*Cost of coal per unit sold		1·21d.
Cost of a unit sold if capital had not been repaid		3·4d.
Cost of a unit sold with capital repaid, and maintenance		5·18d.

* This was more than it should have been.

The year 1893 was exceptionally free from fogs, and those which occurred were, I believe, chiefly on Sundays. This led to the receipts for current per lamps installed for that year being below what may be expected over an average number of years. In considering the foregoing Table, it should be remembered that the capital repaid is in respect of the cost of a site, the cost of mains, permanent charges, &c., for the supply of a far

Digitized by Google

greater number of lights than those which were supplied during the year, so that, in future years, the cost of production will diminish, inasmuch as the fixed charges and repayment of capital will be spread over a much larger output.

The question of the terms of repayment of the capital for electric lighting by municipal authorities is now receiving serious consideration, as affecting the price at which the public can be supplied with current. The view the St. Pancras Vestry take is, that the repayment of capital should be spread over a period of 42 years, and that renewal should be met out of profits supplemented, if need be, by a rate or loan, when the extent of the expenditure justifies it being spread over several rates, by which the present generation of ratepayers would be able to have the benefit of cheap electricity, which it could not otherwise have.

It is often stated that the cost of public lighting by electricity is greater than by gas. If the same standard of illumination had to be obtained by gas as by electricity the statement would not hold good. It is entirely a question of whether or no the standard of lighting does not require to be raised. I think it does. The present lighting of the thoroughfares in the metropolis is a reproach, and St. Pancras has led the way in reforming this. I am confident that at no distant date the present inefficient lighting of the streets will be looked back upon as comparable with the old oil-lamps for which gas was substituted at a great increase in cost of public lighting.

The destruction of town refuse is now recognised as about the best way of getting rid of it, both from a sanitary and financial point of view. The heat produced by the combustion of the refuse can be advantageously utilised for various purposes, amongst others for generating steam. This has led to the combination of a refuse destructor and electric-lighting station, where the heat produced during the time of working the destructors can be applied to do the work of light loads or in aid of steam boilers. I am now, in conjunction with Mr. William N. Blair, the engineer of the St. Pancras Vestry, carrying out a combined destructor and electric-lighting station at King's-road, to serve other parts of the district, the outlay on which will be about £40,000 without distributing mains, which will connect it with the existing network, and will enable the heat produced during the day time to be utilised to do the work of charging the batteries and the light load over the whole district.

Having described the satisfactory results that have already been accomplished, I am confident that it only requires ordinary good administration for a still further degree of success to be attained, which will enable the Vestry either to lower its rate of charge below 6d. per unit, or to have a handsome amount each year to devote to the benefit of the ratepayers. I desire to record my thanks to the members of my staff, and especially to my chief assistant, Mr. Thrupp, for their aid in carrying out these works. In conclusion, I think the St. Pancras Vestry may be congratulated on the success that has attended their enterprise, which has fairly realised the anticipations and calculations upon which it was promoted.

ELECTRICITY SUPPLY IN BERLIN.

The Report of the Berliner Elektricitätswerke contains an interesting summary of the working of that concern up to June 30, 1893, and a brief *résumé* of it may be of value to English engineers. A gratifying increase of business and improvement in the supply has taken place, the number of lamps (30-watt) having risen from 272,000 to 328,000; while the output has advanced from 45·9 to 53 million ampere hours, excluding the amount consumed by the stations themselves. The following table gives the consumption since 1885 (we have translated the figures into kilowatt-hours, as they are very confused in the report) :—

—	Private lighting.	Street lighting.	Industrial power supply.
Aug. 15 to Dec. 31, 1885.	38,150	—	—
1886	303,120	3,054	—
1887-88	715,920	6,282	—
1888-89	1,173,730	19,962	12,956
1889-90	2,511,000	21,646	69,591
1890-91	3,554,400	21,8[illegible]4	274,457
1891-92	4,831,440	21,708	186,611
1892-93	5,228,600	21,576	238,042

The receipts on all heads were 3,570,696 marks (£178,535 nearly), an increase of about 8½ per cent., in spite of the reduction of the tariff in January. The use of motors has increased very considerably, from 121 with 500 H.P. to 232 with 785 H.P., nearly 60 per cent.; and they are still increasing equally fast.

Considerable economies have been effected in works' costs: coal has been reduced 23 per cent., oil 43 per cent., salaries 18 per cent., sundries 1 per cent., making a total decrease of 15·6 per cent. in the works cost per I.H.P. (probably I.H.P. hour is meant); and a further economy is to be produced by replacing at the Mauerstrasse station three 250 H.P. engines and dynamos by one 1,200 H.P. steam dynamo. An extension of the mains to the Zoological Gardens quarter has proved very successful, more than 22,000 lights having been applied for.

The position of the various accounts is then discussed, noteworthy being land account, £30,500, mains £34,000, and machinery and plant £19,000. We note that the motor account has risen considerably, the Company apparently doing a considerable business in the hire of these machines. We note also that the system of regulating clocks worked by the Company, and regulated automatically daily, which we recently referred to in these columns, is now working satisfactorily. The Company owes the large sum of £35,800, chiefly to the Allgemeine Electricitäts Gesellschaft.

After deducting from the gross receipts all cost of working, interest and repairs, there remains as net earnings 1,089,376 marks (about £54,460), which the Directors propose to divide as follows :

Reserve fund	54,468	marks,	about	£2,720
Dividend at 8½ per cent.	765,000	,,	,,	£38,250
Share of profits payable to Municipality	91,670	,,	,,	£4,580
Special renewals fund	50,000	,,	,,	£2,500
Percentage to Directors and Managers	76,500	,,	,,	£3,825
Bonuses to Staff Pension Fund	38,250	,,	,,	£1,912
Workmen's Union	3,000	,,	,,	£150
Carried forward	10,487	,,	,,	£524

The Company's share capital is nine million marks, about £450,000. As regards the prospects of the Company, it is remarked that at the end of September 96,000 amperes were taken up or applied for, the capacity of the stations being 130,000 amperes.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 16th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28 Victoria-street, S.W. Discussion on Prof. G. Forbes's Paper on "The Electrical Distribution of Power from Niagara Falls."

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Bacon's Key to Nature," by Prof. Nichol, M.A.

SATURDAY, February 17th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

TUESDAY, February 20th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion: "Forging by Hydraulic Pressure," by Ralph Hart Tweddell, M.Inst.C.E.

WEDNESDAY, February 21st.

ROYAL METEOROLOGICAL SOCIETY.

8 p.m. Ordinary Meeting at 25, Gt. George-street.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Meeting at 20, Hanover-square, W.

SOCIETY OF ARTS.

8 p.m. "Electric Signalling without Wires," by W. H. Preece, C.B., F.R.S.

THURSDAY, February 22nd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. The following Papers will be read: (1) "A Method of Testing the Magnetic Qualities of Iron," by Gisbert Kapp, M.Inst.C.E. (2) "A Note on Parallel Working through long lines," by W. M. Mordey, Member.

FRIDAY, February 23rd.

PHYSICAL SOCIETY.

5 p.m. The following Papers are down to be read: (1) "A Method of determining Refraction Indices," by W. Littlewood. (2) "A New Electrical Theorem," by T. H. Blakesley. (3) The Attachment of Quartz Fibres," by Prof. C. V. Boys.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting at 25, Gt. George street. The following Paper is down to be read: "Ship Slipways," having special reference to the Dover Slipway, by Walter Beer, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Transformations of Electric Currents," by Prof. Silvanus P. Thompson, F.R.S.

THE CITY OF LONDON ELECTRIC LIGHTING.

The Paper which was read in part by Major-Gen. WEBBER at the Institution of Electrical Engineers on Thursday last, deserved, as the President remarked, better treatment than was accorded it by the meeting. The Paper was in the hands of some of the members on Thursday morning, so that the only chance of securing a useful discussion was by adjourning it until the next meeting. As this was not done, doubtless for good reasons, the critical examination of the Paper was thus lost. The answer to a question asked by Mr. KAPP, but not given in Gen. WEBBER's reply, is, we believe, that, according to the original design, the low-tension mains were not to be connected, but that each network served by one transforming station should be independent; and that a high-pressure concentric main should be laid between the neighbouring transforming stations, so that they might help one another in case of the failure of the direct mains from the generating stations. To what extent this has been actually carried

Digitized by Google

out we have no information. The remarkable reticence about this work is doubtless due to the fact that the first part of the plant was put down in a great hurry to make some sort of show before the period within which the public lighting had to be completed expired, and that much of the subsequent work has been tentative or experimental. Some day, when, perhaps, nearly all interest has disappeared, an account of the results will be given. Mr. KAPP did not see the advantage of discontinuity of the supply networks, but a great advantage surely is to be found, as we pointed out three weeks ago, that earths on one such network will in no way affect leaks on another network. The difference of potential of any network from earth is quite indeterminate, so long as it is completely insulated. One leak, large or small, will put one side to earth, and nothing more will happen. The leak, if serious, would soon be detected, localised, and removed. The only apparent advantages of connection are the equalisation of pressure, in case of an exceptional local demand, and security from extinction in case of a complete breakdown at a sub-station.

The light thrown upon the coal consumption for Brush arc lighters and for Thomson-Houston machines is interesting. The reliability of, and immunity from injury in case of short-circuit of these dynamos has been proclaimed for many years. We have always understood that low-current density and underloading sufficiently accounted for the former virtue, and that the latter depended upon self-induction which wastes no energy, and not upon high resistance. The use of parallel arc lighting has been ridiculed by series arc light men on account of the added resistances. But when five arcs, not Brush lamps, perhaps, nor Thomson-Houston, can be run on 200 volts as at Brighton, or with 90 amperes and 450 volts as at St. Pancras, the current being supplied from really first-rate English continuous-current dynamos, this 7lb. of coal per unit which, we understand, is the lowest that the contractors were prepared to accept, needs a little explanation. The arc lamps are either burning or not burning, and if the plant is run at all it is run on full load. There is no question of load-factor here, unless, indeed, keeping steam up all day in view of a fog is taken into account in making this liberal allowance of coal.

Some rather mild remarks were made by Gen. WEBBER on the intricate financial operations which were the real cause of the delay in getting to work on the City lighting, and of the scramble and inevitable increase of expenditure when a start was at last made. But mild as these remarks were they drew forth a rather angry reply from Mr. J. B. BRAITHWAITE, JR. This gentleman spoke of the unfortunate moment at which money had to be found. BARINGS had just collapsed, and the time allowed for the completion of the public lighting, time which had been wasted in financial haggling, was running out. The contracts for the public lighting of the two first districts were dated May, 1890, but the first sod was not cut until January, 1891. It seemed to Mr. BRAITHWAITE that it was a matter of great interest to electrical engineers that men should have had the pluck to come forward to save the contractors and find the cash to provide, as he rather unpleasantly put it, for the experts' fees. Interesting, no doubt, but peculiarly so to these "plucky" gentlemen who, shortly afterwards, pocketed £25,000 or so, and this, not from the profits of an undertaking to which they had subscribed at considerable risk, but before any business had been begun. One would think, to hear these speeches, that some benevolent deed had been done, something good for trade. What was done was to secure a profit of 50 per cent. on the venture, and to secure for the Brush Company the job for which they had been worrying for years. On November 30, 1891, at the extraordinary meeting for winding up the Pioneer Company, Mr. BRAITHWAITE said that the Company had "stepped into the breach in February last, when things were very dull." The nominal capital of the Pioneer Company was £100,000; but, according to the statutory returns, only £25,000 appears to have been actually called up and paid. And it is these pioneers, with whom "the Lord Mayor, as head of the City, had acted almost as a philanthropist in his desire to serve the City by heading the Board of Directors in promoting the Pioneer Company," who stepped out of the breach with £75,000 eight months after they had stepped in, and whether the bonus was really 50 per cent. as stated, or whether it was 200 per cent. as it would appear to have been, does not really matter now.

Two other speakers supported Mr. BRAITHWAITE on Thursday last. One said that if they were to avoid this sort of thing no large schemes could be carried out. The other observed that the way in which the capital was subscribed was the hardest part of the concern. We do not, therefore, complain, but agree with Gen. WEBBER that the public have only themselves to thank if this sort of thing is necessary. The money was not, in the first place, subscribed for electric lighting, but for a gamble. There was nothing about gambling in the Articles of Association of the City of London Electric Lighting Company; of course there are degrees of gambling: every insurance premium, for matter of that, is a bet that a certain event will not come off. It is an absurd paradox that when money is difficult to raise, the only remedy is to create more difficulties. We hope that the times have not gone by when capital could be raised direct on the merits of an undertaking, and subscribed directly to it on reasonable terms, without being thus bled by a pioneer company. One of the London supply companies was financed in the old-fashioned way, without any "assistance" whatever from middlemen, much to the disgust of this fraternity; another received so meagre a reply from the subscribing public that their direct offerings were, we believe, all rejected, and the Company had to be floated by the underwriters. All engineers and contractors are aware how valuable are the services of "the City" to industrial enterprise, but many promoters talk as if they ought to be thanked for promoting trade. This £75,000, to which we have referred, was part of the capital subscribed for the purpose of putting down electrical machinery and mains. But as to at least £25,000 of it not a penny was used for this purpose, and never came near the electrical trade. It went into the pockets of these "plucky" gentlemen, who worked the pioneer company. This is called pluck. Probably because someone was plucked. We would rather call it luck, and as such, can congratulate them on it.

But we must repeat once more that we do not complain. This mode of procedure appears at present to be inevitable, and so long as the public tamely submit to it, they, and not the financiers, are to blame. Contractors would rather that undertakings were financed thus than that nothing should be done, and very properly. The public are satisfied when at last, after being tossed from one company to another, someone has to do the work, and when dividends are paid. The labourer of to-day has strange delusions about capital, but the company promoter and financier have acquired, if possible, more erroneous views. Labour and capital are necessary to each other; but these plucky and benevolent pioneers ought not really to be necessary, for every thousand pounds that they secure is a thousand pounds that might have been invested reproductively. We hope that the City of London Electric

Digitized by Google

Lighting Company will be as successful in earning dividends by industrial work, as was the City of London Electric Lighting (Pioneer) Company in earning a bonus by financial enterprise. The undertaking is an important one, but nothing to make a fuss about. The remarkable feature of the main laying is the speed with which it was carried out. There does not appear to be anything, either in the distributing or in the generating plant, that could not have been done quite as well by any of our leading electrical firms. To talk about it as was recently done, as though it were a more remarkable undertaking than the Tower Bridge, simply because it has cost more, is to show a lamentable ignorance of both electrical and of civil engineering.

THE LIVÈT REFUSE UTILISER AND STEAM GENERATOR.

The first prominent suggestion of the utilisation of town refuse as a fuel for raising steam and developing electric power was made by Prof. George Forbes at the Edinburgh meeting of the British Association in 1892. Although such fuel had for some time been used for raising steam, it had never been definitely employed for electric lighting purposes. The proposal at Edinburgh came as an adjunct to a scheme of energy storage, which Prof. Forbes advocated as being specially suited to the geological features of "modern Athens"—namely, a scheme of storage based upon the elevation of a large mass of water to a height, in an enclosed system of hydraulic mains. In this paper Prof. Forbes drew attention to a point which is of essential importance in relation to the utilisation of town ashbin refuse for electric lighting, viz., the necessity for burning such a fuel at a high temperature and at a steady rate. To utilise such a fuel for electric lighting would, therefore, necessitate some form of storage being adopted. Various modes of storage have been proposed since the publication of the above-named paper, and among these we may mention the system of thermal storage devised by Mr. Druitt Halpin. It will presently be seen that in the Livèt system a novel form of energy storage is in operation.

The actual value of ashbin refuse as a fuel must be a very variable quantity, depending largely upon the locality, and varying considerably from time to time in each locality. Prof. Forbes, in his Edinburgh B. A. Paper, expressed the opinion that 10lb. of ordinary refuse would equal 1lb. of average coal, and he cited a case where it required 75lb. of such refuse to produce one horse-power-hour. At a more recent date, Prof. W. C. Unwin, in his Howard lectures before the Society of Arts (January and February, 1893), gave some instructive figures bearing on this question. According to the statements there made, it would appear that for the proper sanitary combustion of refuse it is requisite that a very large quantity of air—from 7lb. to 8lb. per pound of refuse—should pass through the furnace grate. Under such conditions as these, Prof. Unwin asserts, it has been found possible to obtain one horse-power-hour by the combustion of 40lb. of refuse.

Engineers who have compared these figures with the usual duty of average coal must have been struck with the inferior quality and wasteful treatment of this form of fuel. The principal causes of this inferior duty are:—(1) The small proportion of actual combustible element in the refuse; (2) the burden of water which it contains, and which it must evaporate; (3) the large percentage of mineral matter, causing clinker and ash, which drops from the grate in a heated state, and may waste a large proportion of the furnace heat; and (4) the great weight of air which must be heated by the furnace and rejected up the chimney at a high temperature. In average instances the percentage of actual combustible will probably not exceed 20 per cent., the burden of moisture in the refuse will be not less than 25 per cent., and might frequently be doubled; while the remaining large percentage would form ash and clinker.

There are, however, circumstances which tend to make ashbin refuse a very valuable fuel; not, indeed, from the thermal point of view, but from the commercial aspect. The fact that the material must be got rid of, and promptly, will always militate against a high price being placed on it, wherever companies may offer to purchase it from vestries; and, at the present time, is sufficient inducement to the latter to willingly pay as much as from one to two shillings per ton to have it removed for them. Again, where vestries are themselves occupied in getting rid of the refuse, it is found that the least expensive method they can adopt is to burn it. This being so, the prime cost and the working expenses of the furnaces are a necessity independently of the utilisation of the furnace heat for raising steam. The additional expense due to the boiler and steam plant is all that can be laid at the door of utilisation; and, it may be remarked, the expense is much smaller than in ordinary cases where coal is burned. Prof. Forbes has commented on the "wise provision of nature" which has made the amount of town refuse just sufficient to give the population electric light. The absurdity of any such balance must be evident when we recollect that this relation depends on the inefficiency of the generating plant—by no means a provision of nature. However, from the fact that refuse may be mixed with superior fuel, such as coke breeze or slack, it will be seen that electric lighting need not suffer from a temporary failure of a supply of refuse, even though the storing of refuse is prohibitive.

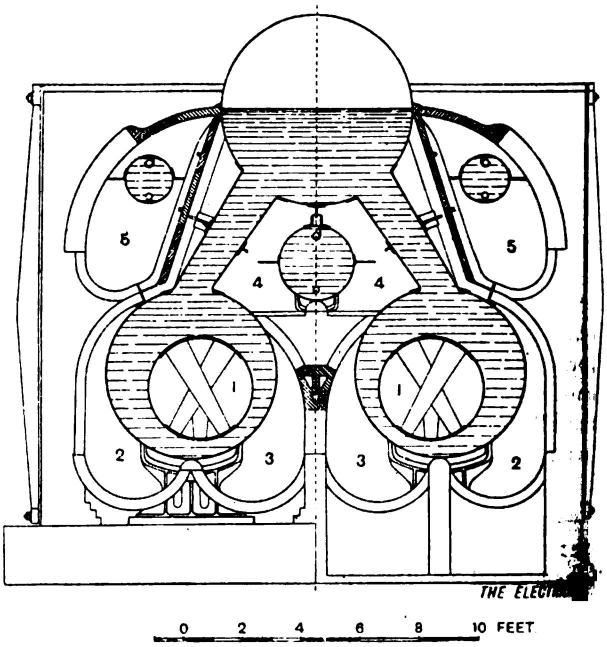

Fig. 1.—Transverse Section showing Setting.

An interesting experiment, conducted on a fairly large scale by the Atlas Contracting Syndicate, at Halifax, in Yorkshire, is one of the latest steps towards the solution of the problem of adapting refuse burning to the purposes of electric lighting. At this town a furnace has been erected, according to the plans developed in the patents of the late M. Livèt. These patents are owned by the above-named syndicate, who purpose developing them for municipal and other electric lighting plant. The principal features of novelty are exhibited in the furnace, though the form of the boiler calls for some description and comment. A transverse section of the entire plant is seen in Fig. 1, while Fig. 2 shows the longitudinal section. The boiler, it will be seen, is of composite structure. There are two separate internal furnaces, as in the Lancashire boiler, each provided with the usual form of Galloway stiffening and circulating tubes; but each of these two flues is contained in a separate cylindrical shell, as in the Cornish boiler; and again, these shells are completely filled with water, and are connected to a large steam drum or evaporator by means of a number of vertical return tubes, as in the elephant boiler. In addition, there are three small water cylinders, which act as feed water heaters, or economisers, which are placed in the external flues,

Digitized by Google

and which are connected together, and with the main feed pipe, in the manner shown in the front and back elevations (Figs. 3 and 4). It will be noticed that the internal furnaces are stayed eccentrically with the shells in which they are placed. The object of this is to produce rapid circulation, by giving more heat to the water one side than on the other. It seems doubtful if, with the Galloway tubes in the internal flues, the circulation will be very much improved by this device; while the serious strains that will arise from irregular expansion must weaken the shell, increase the risk of explosion, and reduce the life of the boiler. This type of boiler has the merit of a large water room and an extensive evaporative surface; moreover, the water level is several feet above the furnace crown, a fact which enables the boiler to do abnormally heavy duty for a considerable time, with no risk of "bringing down the firebox." The ratio of total useful heating surface to the grate area is stated by Mr. Glaskin, the engineer to the syndicate, as being 50 times the grate area; as against 30 or 35 times in the usual Lancashire type of boiler. But it must be remembered that the boiler includes the feed-heater or economiser, the surface of which is not usually included. During some short experiments which we witnessed, in which no actual measurements were made, it appeared that the average thickness of fuel on the grate was about 10 in., the fuel being stoked by hand on the spreading system.

The Livèt furnace has been designed to facilitate draught; but in this particular plant it has been modified to suit the special requirements of the fuel. In its ordinary form the

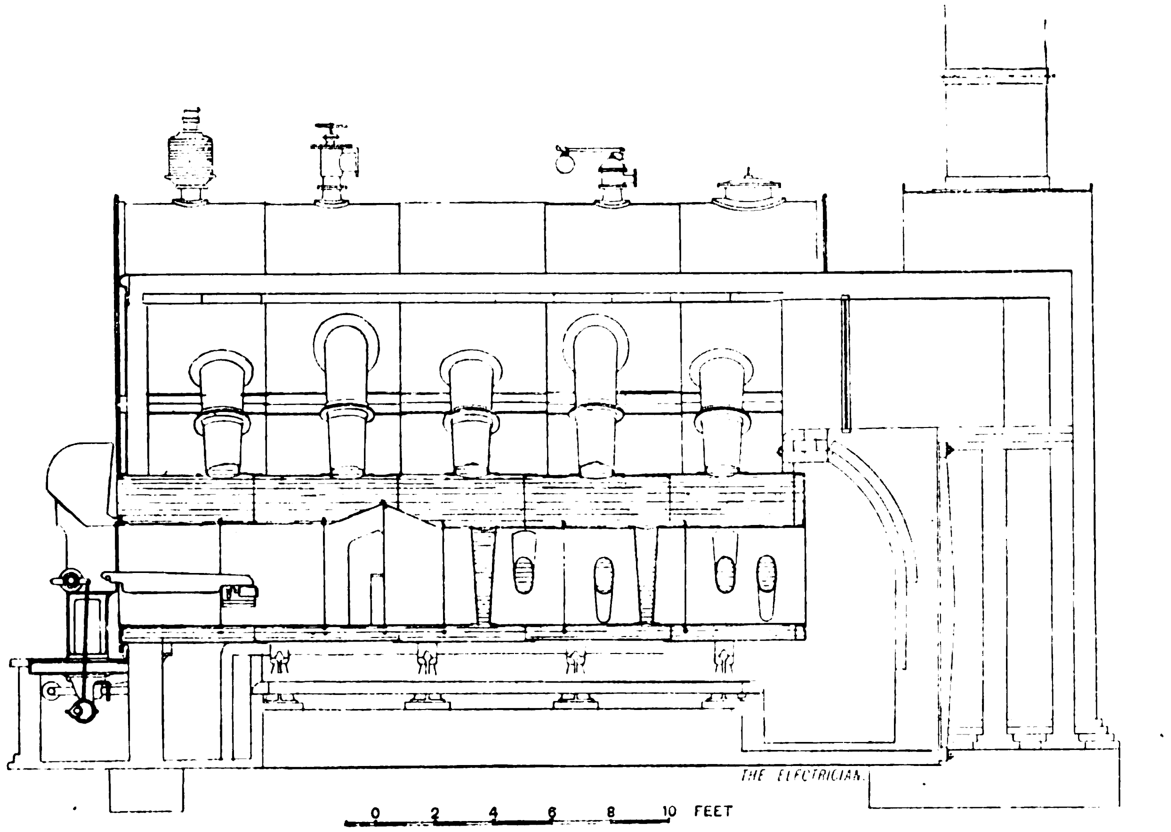

FIG. 2.—Longitudinal Section.

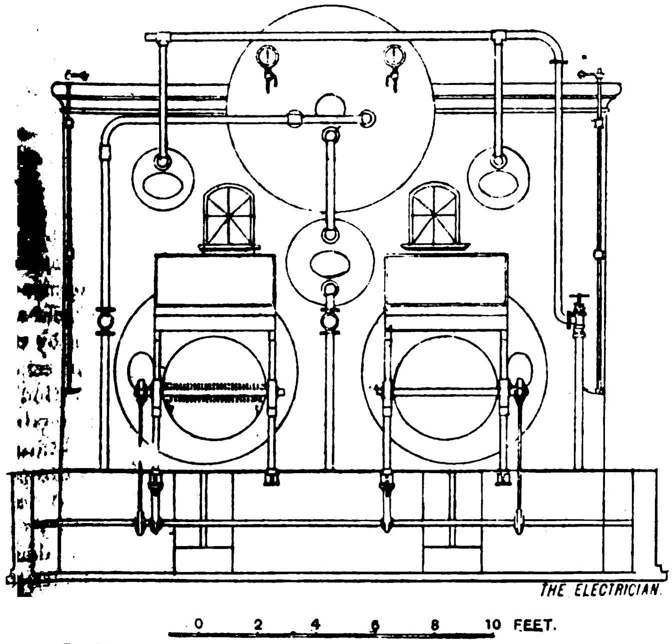

FIG. 3.—Front Elevation, showing Mechanical Stoker and Feed-Pipe Connections.

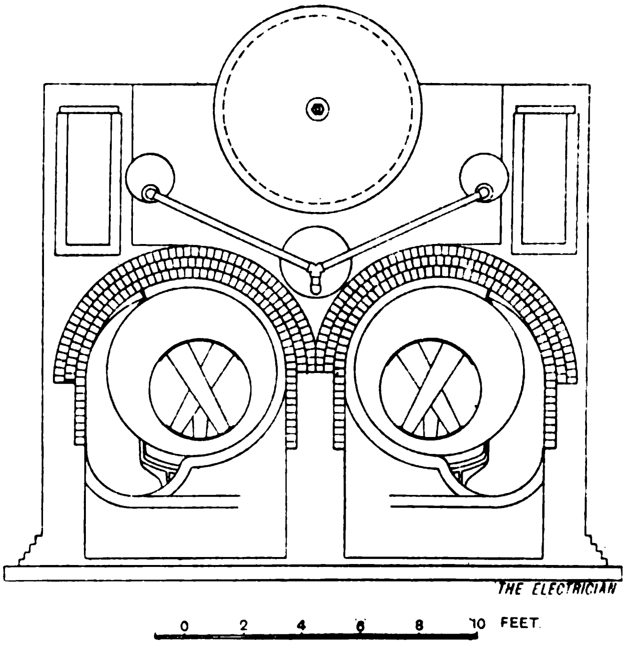

FIG. 4.—Back Elevation, showing Cross Connections for Feed-Heaters and Mud Drum.

Digitized by Google

Livèt flue is systematically expanded in section from the furnace to the top of the chimney. That is to say, if we refer to Fig. 1, we shall find that the gases first pass to the back of the boiler along the internal flues (1), then forward along the external flues (2), then to the back again by (3), then by (4), and finally they reach the smoke chamber and the chimney *viâ* (5). In each succeeding flue the sectional area is increased; moreover, the volume of the gas is diminished by cooling, so that the velocity is continuously reduced. The effect of these conditions is, therefore, to transform a part of the velocity-head into pressure-head, resulting in an onward pressure on the advancing gases. If this is done gradually and without shock, it is found to materially add to the effective draught. In the Halifax furnace, however, there is a sudden and enormous expansion of the flues at each end of the boiler, for here the flues lead into chambers for receiving the dust which

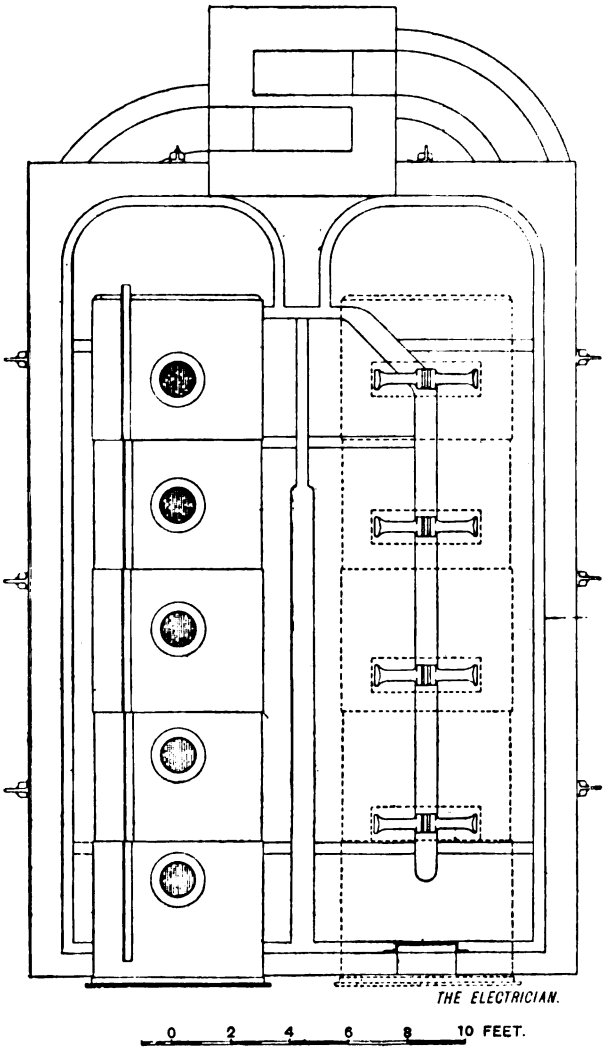

Fig. 5.—Sectional Plan, showing Setting.

the in-rushing gases sweep from the grate. Entering these, the gases suddenly slacken in speed, and deposit the suspended solid matter. It may be that it is necessary to sacrifice some of the efficiency of the draught in this way in order that the useful heating surface may be kept clean; but we cannot help pointing out that this practice must materially check the passage of the gases through the flues, and reduce the draught-power of the chimney. The height of the chimney in the present instance in 110ft.; it is constructed of bare wrought iron. The initial temperature in the chimney averages 300°Fah. for refuse burning, and 350°Fah. for coal burning. The accompanying Fig. 5 shows the mode of setting the boiler, the lower shells resting upon a series of cast-iron stools, which are also shown in Fig. 1. The flues belonging to the left half of the boiler are partitioned from those belonging to the right half, the gases circulating independently until the chimney is reached. The Vicars mechanical stoker is shown in some of the accompanying drawings, as this is used when coal slack is burned. With town refuse in its ordinary state, it is, however, impossible to use a mechanical stoker.

We have already commented on the need for ample storage in conjunction with refuse utilisers, when the latter are used for electric lighting. The character of an electric light station load diagram is too well known to require description. In order to meet the very widely-varying demand for power, and at the same time to consume the refuse at the high temperature which sanitary considerations dictate, Mr. Glaskin has devised a system which he has named "coal storage." In this system the refuse is mixed with coal slack in varying proportions, as occasion may require; when the load is great the proportion of coal being great; when it is small, the coal being absent or in small proportion. While this method must undoubtedly tend to get over what is a very great difficulty in electrically utilising refuse, it does not entirely surmount it. For "coal storage"—if we adopt the name—has neither the elasticity nor the durability which is required; it is neither capable of dealing with long periods of absolute idleness followed by short periods of great activity, nor is it competent to cope with any large sudden change in the load. Combined with a very large water room, such as is offered by the Halpin system, or with electrical storage, "coal storage" might be found to answer well enough.

We must now consider some of the specific claims which have been made by the Syndicate, and by their engineer in his report which lies before us. We notice first a small table giving the evaporative performance of the Livèt boiler, as compared with the performances of Lancashire boilers. Here it is:—

"It will, perhaps, be most to the point to quote the summary of trials made with Lancashire boilers by Sir Lyon Playfair and Prof. de la Bèche. under instructions of the Admiralty, and of Mr. Lavington E. Fletcher for the Lancashire and Cheshire Coal Association:—

	Pounds of water evaporated per pound of coal.
Playfair and de la Bèche	8·13
L. E. Fletcher	10·77
Livèt	13·13."

Each of these tests was made with coal alone. Whatever may have been the origin of each separate item, we can only characterise the bald collection of the three items in this table as highly misleading. We fear that the engineer has not been careful to see that he is comparing things which are under similar conditions. To offer the performance of a Livèt boiler and feed-heater by contrast with the performance of a Lancashire boiler destitute of a feed-heater is scarcely a fair basis of comparison. Again, the figure given on the authority of Messrs. Playfair and de la Bèche is by no means as high even as the average figure obtained by these engineers, in their Admiralty series of Lancashire boiler trials. Moreover, if we remember rightly, the trials of Lancashire boilers cited in this table were made as long ago as 1850-67, and are by no means comparable with modern performances. In passing, we may mention that Mr. L. E. Fletcher obtained a performance in Lancashire boilers, without an economiser and *without the use of the external flues*, better than the 8·13lb. given by the engineer as representative of these boilers under fair conditions. Mr. Fletcher also obtained an average evaporation of 11·56lb. in Lancashire boilers with economisers. In modern times an evaporation of more than 12lb. is commonly obtained in these boilers. The 13·13lb. given in the table as the performance of the Livèt boiler means nothing at all, until the conditions of the trial and the quality of fuel have been exactly stated. We very much doubt if anything like this performance could be obtained under the usual conditions in which engineers are accustomed to make boiler trials. With coal having a theoretical evaporation of 14lb., this figure means that the Livèt boiler is credited with the incredibly high efficiency of nearly 94 per cent., the radiation, clinker, chimney, and other losses being only 6 per cent!

It is to be regretted that the interests of this invention have been prejudiced by such comparisons, for these can do no good to what is, without doubt, a genuine and satisfactory

Digitized by Google

attempt to solve the problem of the utilisation of dustbin refuse. That this refuse is a good basis for steam production there can be no doubt; that the Livet boiler can utilise it steadily, and with the production of no noxious fumes, there is also no doubt. But it yet remains to be shown that this fuel, when consumed in this type of boiler, can be adapted to the peculiar conditions of electric power generation. It is to be regretted that attempts have not been made to imitate these conditions, and to ascertain exactly the performance of this steam generator when placed under them for an extensive period.

SOME NOTES ON THE ELECTRIC LIGHTING OF THE CITY OF LONDON.*

BY MAJOR-GEN. C. E. WEBBER.

To the industry generally the history of the inception, and of what led up to the accomplishment, of the public lighting of the streets of that part of the metropolis known as the City of London may have, for several reasons, a special interest, and be worthy of record. By those who may not already know it, it should be understood that the Commissioners of Sewers hold a similar position, and have similar powers to those that were possessed by the Metropolitan Board of Works and by the London Vestries before the London County Council came into existence; in fact, they are the local authority, possessing jurisdiction distinct from that of the Corporation, the Common Council, the Bridge House Committee, and such bodies; having the direction and control of expenditure on works, for which purposes their engineer and surveyor is Mr. William Haywood, C.E., a gentleman distinguished no less as a colonel of volunteers, late and for many years commanding the 1st London Rifle Volunteers,† than as an engineer. I think there is a good deal in which the question of what led up to the lighting of the City by electricity so much differs from ordinary cases, that a slight sketch of its history—which has never, I believe, been published—is not out of place on the present occasion. The City is at the head of our municipal institutions, both as regards antiquity, wealth, and organisation. From an imperial point of view, it is regarded as the heart of the commerce of the world. In respect to public lighting by electricity, I believe I can show you that it also has taken the lead.

In 1878, when the Municipality of Paris celebrated the International Exhibition of that year by lighting the Avenue de l'Opera with Jablochkoff lamps, run with Gramme machines by the Société Générale d'Electricité, Mr. William Bassingham, deputy-chairman, and Col. Haywood, engineer of the Commissioners of Sewers, severally reported to the Streets Committee, in such detail, and in such terms, as to ensure the question never being dropped until the accomplishment of the results which we can nightly witness at the present time.‡ It is nearly 15 years since the date of those reports—years that have been momentous to all of us electrical engineers.

Col. Haywood's report could not have dealt more exhaustively with the question, subject to the difference in knowledge at the present day, than if it was now to be compiled. He pointed out that no section of the metropolis was more interested than the City in obtaining an efficient illuminant, for, that within its boundaries the Gas Light and Coke Company then collected a rental of £370,000 per annum. No doubt that example of street lighting in Paris induced the Commissioners to take up the subject. The 64 electric lamps in a thoroughfare 980 yards in length, placed 30 yards apart on alternate sides, were said to give a nominal candle-power of 20 times that of the 300 gas lamps previously used, allowing that one Jablochkoff candle gave 100 times as much light as a gas burner using 12-candle gas at 5ft. an hour. The cost price of these lamps (estimated then at 6d. an hour, as they were extinguished at midnight) was £50 a year each, which, for 64 lamps, came to £3,200 a year, as against the cost of the gas lighting during the same hours, which came to £1,200 a year at 5 centimes per gas lamp an hour. Colonel Haywood at that time considered that the Avenue was lighted "vastly in excess of all reasonable requirements"; and although he went no further than stating that in his opinion there were places in the City—such as by King William's Statue, in front of the Mansion House, and in the Circuses—where the convenience of the large traffic "might justify the expense of employing the electric light during the busiest hours of darkness," he nevertheless recommended the Commissioners, "that as early as possible an ample experiment be made by lighting with electricity during the winter months of 1878 one or more of the public thoroughfares within their jurisdiction." In consequence, in November, 1878, the same company commenced lighting the Holborn Viaduct with 16 Jablochkoff lamps, placed about 110ft. apart. They were run from sunset till midnight, replacing 86 gas lamps.* The results arrived at after three winter months' work were, that, while only doubling the light (allowing a loss of 50 per cent. with the globes) of the 86 gas lamps, the cost—namely, 5·73d. per hour—of 16 Jablochkoff lamps was four times that of gas at ¼d. an hour.

The discouragement produced by this experiment only continued for one year, and in the spring of 1880 the Commissioners (at the instigation of several members whose names have since been connected with improvements in lighting the City) again decided to renew experiments on a more extended scale by lighting New Bridge-street, Queen Victoria-street, Queen-street and Queen-street Place, King William-street to the Bank, Poultry, Cheapside, St. Paul's Churchyard, Ludgate Hill, New Bridge-street and the Bridge. The thoroughfares in which the trials were to be made were divided into three districts, and out of six competitors who tendered in October, 1880, the following were selected, and the year's work lasted from April 1, 1881, to April 1, 1882:—The Blackfriars Bridge district to the Brush Company; the Southwark Bridge district to the Electric Light Power Generator Company (Lontin system); the London Bridge district to Messrs. Siemens. Col. Haywood reported in June, 1882, that, allowing 50 per cent. of loss through the use of globes in the several districts the increased light afforded, and the cost of the same under the tenders, in proportion to that of gas, were—

	Increased light.		Relative cost.
No. 1 (Brush)	15	......	About the same.
No. 2 (Lontin)	14	......	Twice.
No. 3 (Siemens)	13½	......	3¾.

Thus the City of London had taken the lead in making a practical experiment on a large scale.†

The encouragement afforded by the results may be estimated by the following:—(*a*) The Commissioners decided to experiment again in four additional areas, and, calling for tenders, received, in May, 1882, offers from eight firms. In one tender only was the question raised of supplying light for private consumption. (*b*) Messrs. Siemens's offer to continue lighting No. 3 district at £3,600 a year, being an advance of £1,330 on their original contract, was declined, and that firm retired from the City. (*c*) An arrangement with the Brush Company to continue for another year lighting No. 3 district at a cost of £800 per annum was made.

But, as we all know, the Electric Lighting Act of 1882, which obtained the Royal consent and became law in that year, appeared, and with it a flood of applications for Provisional Orders and Licences, three of which covered the area of the City, and obliged the Commissioners to hold their hands and consider the position in which the Act placed them, after having already had the subject in hand for nearly four years. In November, 1882, the Streets Committee of the Commissioners of Sewers consulted Mr. Preece; and I shall take this opportunity to remind him of a statement he then made, and has since repeated, on the subject in which, I am happy to be able to say, he showed an accuracy of foresight in which later experience has fully supported him. At that date he wrote:—"I know of no branch of engineering where more forethought is necessary to calculate all the contingencies likely to be met with than a system designed to illuminate a large city like that of London."

Meantime, an experiment with public lighting by glow lamps had been in progress. In April, 1882, the Edison Company commenced an experiment with that means of illumination on the Holborn-viaduct for a length of 466 yards, upon which Col. Haywood reported after a twelvemonth's run. Ninety-two 16-c.p. glow lamps replaced the gas burners in the existing street lanterns, 86 14-c.p. gas batswing burners being displaced. The result in light and cost was that the electric lighting contractors gave 1¼ times the light at the same price as gas—namely, £4. 10s. 4d. per burner per annum. That this experiment led to but negative results we all know. If it showed anything, it was that the substitution of a glow lamp in the ordinary street lantern for the lambent flame of a gas jet, so that the incandescent filament is directly visible, is a very poor and unintelligent application of the electric light, and puts it in a position in which it is at a great disadvantage in comparison with gas. I believe that the glow lamp for public

* Paper read before the Institution of Electrical Engineers, February 8, 1894.

† Colonel Haywood joined the corps in 1859 as a private, and rose through each rank to be Lieut.-Col. in 1876, and retired from that position in 1882.

‡ As international juror for telegraphs and allied electrical applications of that year, my notes on the installation show that the Avenue and Place de l'Opera, and the Place du Théatre Français, only represented a small fraction of the application of the Jablochkoff lamp then running in France.

* At the same time the Metropolitan Board of Works had been making experiments with the same Company's plant on the Victoria Embankment, including photometric comparison of the gas and electric light.

† It was estimated to cost over £8,000, but, through the inability of the contractors in No. 2 to commence lighting in time and for other reasons it actually cost about £5,400.

Digitized by Google

lighting purposes never quite recovered from the results of that experiment.

The City was one of the earliest areas upon which the electric light manufacturing companies set their eyes. Hardly had the 1882 Act become law when, as I have said, three companies commenced applications for Provisional Orders. As still now occurs, the local authority took alarm, and began to investigate the subject for themselves. Most complete reports as to the law, engineering, and science of the question were made by Mr. Baylis, Col. Haywood, and Mr. Preece. These gentlemen may be said to have been amongst the very first to compile information for a local authority on the subject of electric lighting; and, although ten years have passed, the terms they used, conclusions arrived at, and recommendations made, differ very little from those that have since, and up to this date, been, and are being, laid before similar governing bodies for their information and guidance. The general tenor of the recommendations made in 1883, especially by Mr. Preece, were that the Commissioners ought to obtain their own Provisional Order or Licence, and, either by contractors or by their own officers, to carry out the undertaking for themselves, both for public or private supply. The consequence was that in March, 1883, the Commissioners decided to apply to the Board of Trade for the necessary Licence under the Act of 1882, for the whole City, having in its terms a compulsory area of a limited size, and to oppose all other applications for Provisional Orders and Licences under the Act of 1882. Although tenders from a number of electric light manufacturing companies were called for and received, it is of moment to note that Mr. Preece reported that their terms were all "eminently unsatisfactory." No doubt his criticisms were correct, but, as the length of time of the proposed contract was limited to seven years, it is not surprising that they were not such as could be accepted. The lowest and highest offers for each public light arc lamp were £36 and £71 per annum respectively. In spite of amendments in those proposals, Mr. Preece could still find nothing to recommend them; but we, who look back to what has transpired in the interval, can realise that all proposals made in those days, when the security offered was such that capital recoiled from it, were neces sarily wild and unsatisfactory, and were mostly made by firms who, if they were sound, must have secretly hoped never to be called on to carry them out.

Meantime, the Anglo-American Brush contract for lighting, for about 4,030 hours per annum, New Bridge-street, Ludgate-hill, and St. Paul's-churchyard still ran on, and was costing the City at a rate of less than £25 a lamp. Then, in 1883, commenced a period during which companies proposing to obtain statutory powers within the City were kept at arm's length, and during which, Mr. Preece, instructed by the Commissioners, made experiments on the subject of public lighting by arc and glow lamps, partly with the aid of the Anglo-American Brush and Edison contract installations then running. In 1883 he reported "that, while the arc lamp is admirably adapted for the illumination of large spaces, the glow lamp is eminently adapted for our streets and narrow thoroughfares." Mr. Preece's report to the Commissioners of Sewers, of August, 1884, while being very exhaustive as to the whole question of electricity supply generally, is certainly also the standard report on the subject of public lighting. He then stated, however, that "the lamp which, in my judgment, best lends itself to street lighting is the glow lamp, and of the glow lamps I prefer the 50-candle lamp for the main thoroughfare." Notwithstanding the Holborn experiments, Mr. Preece recommended further trials of public lighting with glow lamps, combined with a means of distribution for private lighting within a small area that would require about 5,000 private lamps, at a cost to the City of about £40,000. He also brought very prominently to notice the very valuable proposals of Mr. Trotter connected with his dioptric lantern, to which I shall myself allude later on. These further experiments were never carried out, but I think the meeting will be glad to hear from Mr. Preece if any modifications would now be admitted into his views, on a subject which the meeting is aware is not yet satisfactorily settled.

For more than a year the subject slept.* At that time it fell to my lot to be placed in engineering management of the Anglo-American Brush Electric Light Corporation, and since then, up to July, 1892, I was intimately acquainted with all that has gone on connected with the lighting of the City of London.† The original contract of 1881 of that Company for lighting New Bridge-street, Ludgate-hill, and St. Paul's Churchyard, with arc lamps, still ran, but there were many outward signs of considerable repairs being necessary in the mains. These mains had been laid into the district under the roadways from the Brush Works in Belvedere-road, along Bankside, and over Blackfriars-bridge, and they consisted of two circuits of 7-16's drawn into the same cast-iron pipes, with insufficient draw-boxes and means of inspection; although the insulation was sound throughout the greater portion of their length, there were many points at which it had been attacked, by the pipes having been hastily laid where they were exposed to soil saturated by sewage liquids and other gases and with insufficient means of access for localisation and removal of faults. The currents were generated by Brush arc dynamos, old-pattern armatures, having belt-gearing, to engines, which, with the boilers, formed part of the power which was used in the Brush factory, on which the demands were irregular and occasionally very heavy. The fact was that the Brush Company, when they tendered for the work in 1881, understood it was to be an experiment, out of which little or no actual profit could be expected, and little thought that arrangements which would have been good enough for twelve months would be continued by the City authorities for five years, only terminating through the initiative of the Brush Company, and by the permission of the Commissioners, in December, 1885.

No public body has probably taken more pains than the Commissioners to weigh carefully the *pros* and *cons* bearing on the question of their becoming themselves the undertakers for supplying electricity;* and I think now that, but for the host of offers, merely speculative and otherwise, which was being continually sent in to them and diverting their attention from the issues most in the interests of the ratepayers, they would in the end have decided on raising the necessary capital to do the work themselves.

In November, 1885, a set of proposals was formally made by the Brush Company to contract for the public and private supply of a district of the City, and this was considered by a committee, of which Mr. J. C. Bell was chairman. This was the first practical arrangement on a large scale that had ever come before the Commissioners, and its terms are almost *verbatim* those that were eventually adopted in January, 1889, as the conditions under which the Commissioners would receive tenders. From that moment the question of the lighting the City made a fresh start on a tangible basis as to cost and mutual advantages; and, although it took five years to mature, there was no longer any serious question of the Commissioners themselves becoming the undertakers. In 1886, 1887 and 1888 the matter was again from time to time before them, and throughout that time it was due to the personal exertions of some enlightened members of the Streets Committee that the matter was kept continually to the front.† One of the reasons for the delay was due to a great reluctance on the part of the Commissioners to permit any company to have a Provisional Order within its area of control. The chief reason for this was the condition of things at and below the surface. The occupation of the subsoil by sewers and subways, by the systems of gas, water, and telegraphs, and by various other objects, is entirely exceptional. They would have much preferred that all powers for the disturbance of the surface should be conferred by themselves only, and not by statute. There is no doubt that the ratepayers of the City would now be in quite as good a position if no Provisional Orders had been granted, and if only the contracts that were eventually entered into between the Commissioners on the one part, and the Brush Company and Messrs. Laing, Wharton and Down on the other, were existent. Owing to more than the ordinary rights of user of the soil of thoroughfares and streets being vested in the City Corporation, statutory powers were not necessary to enable them to grant way-leave.‡

In February, 1888, the Commissioners called for a report giving a *résumé* of all that had been brought before them in the previous ten years, and I must here say that it fully establishes the claim of the Brush Company that a large share of the credit for the eventual results was due to their persistence in holding the ground when all others had retired, and in keeping the subject always before the local authority in a manner and in terms which, by their moderation and practical sense, were bound in the long run to commend themselves to business people. The object of this report was to show that the successful use of arc lamps for illuminating large spaces had asserted itself all over the civilised world.§ The advantage of having a contract with a company to supply current to public arc lamps at 3·1d. per unit, including trimming and carbons, instead of at 8d. exclusive of the same—the usual price in Pro-

* In November, 1885, a well-known writer reported to the Commissioners:—"At the present time there is a complete stagnation in electrical enterprise in England, in such enterprise as would undertake the supply of electricity upon a large scale for public and private purposes in towns."

† My own connection with the public lighting of the City of London dates back to the sixties, when I assisted the late Dr. Letheby, City Analyst, in a series of experiments connected with carburetting gas for street lamps.

* So late as April, 1890, they deputed Mr. Preece to report to them on the electric lighting of the public streets of Taunton with arc and glow lamps.

† Mr. Frank Green, Mr. J. C. Bell, Mr. Graham King, Mr. Bridgeman, Mr. Pannell, and others.

‡ There is ample experience to show that if much of the Act of 1882 had been repealed, so far as the metropolis was concerned, as was more than once urged on the Board of Trade, this and many geographical and other anomalies which have kept up, and will for many years keep up, the price of electricity in London, might have been avoided.

§ The successful lighting on a large scale by the Brush Company of the Colonial, Manchester, and Glasgow Exhibitions was described.

Digitized by Google

visional Orders—was dwelt on. The unsatisfactory nature of the proposals made to the City by other parties was fully exposed. The great advantage to the City if the terms of the form of contract originally proposed by the Brush Company in 1885 were adopted, and the misrepresentations which suggested monopoly that had been made, were dispelled; and, it is a remarkable fact, that the then proposed charge of 1s. per unit for private lighting was not considered excessive in view of the circumstances of the probable demand for business premises in the City.

January, 1889, found the Commissioners, again and finally, roused to activity by the Electric Lighting Act of 1888 (due to the personal exertion of Lord Thurlow, the Chairman of the Brush Company), and, the City having been divided into three districts for the purpose of the contracts, tenders were publicly called for; and it may here be remarked that the Company, which, during eight years, had done so much to keep the matter before the public, at that moment was in no better position in March, 1889, as regards tendering, than any other firm which was then only dealing with the matter for the first time.* But yet another stage of opposition had to be got over before the final arrangements for this great undertaking could be said to be on a satisfactory footing. Major Marindin, in April, 1889, had reported against the claim of the City to be exempted from the operation of the Electric Lighting Act, and had, in face of the opposition of the City, recommended the approval by the Board of Trade of the applications for Provisional Orders from two of the above-named companies. The Brush Company had for several years, in deference to the views held by the City authorities, refrained from making applications for Orders, and therefore their absence from the list of applicants in 1889 was intelligible. In the terms of Mr. Preece's report on Major Marindin's contention, the City had been "regarded merely as a local Vestry with some ancient rights that have to be respected"; and that "the amount of lighting and the capital necessary to be expended in the City, which far exceeds that for any other portion of the metropolis," had been overlooked. Major Marindin, by his recommendation, had neglected not only the geographical part of the question, but the fact that the Commissioners of Sewers had been for years studying and experimenting on the question of effective public street lighting.

The tenders for public lighting the main thoroughfares with arc lamps, which eventually were reported on in November, 1889, by Mr. Preece and Col. Haywood, were:—

The Metropolitan Electric Supply Company's revised tender to light the Western district with 121 lamps at £26	£3,146
The Anglo-American Brush, the Central district with 138 lamps, at £26	3,588
The London Electric Supply Corporation, with 136 lamps (half the lamps being extinguished at midnight), at £24. 2s.	3,290
Total for the main thoroughfares	£10,024

and the acceptance of these was recommended.

But of them the Brush Company alone (consistent with their original proposal) had not applied in 1889 for a Provisional Order, and had agreed to the division of profits under a sliding scale—namely, that if the profits exceeded a cumulative dividend of 10 per cent. per annum upon the capital invested, the excess was to be divided equally between the contractor and the consumer—and also had agreed that power should be reserved to the Commissioners to acquire the undertaking and works by purchase at the end of 21 years, in all other respects in accordance with Section 2 of the Electric Lighting Act of 1888. Meantime, no Provisional Orders had been granted for any part of the City area, owing to the withholding of the usual recommendations from the Local Authority which the Act requires. But on the last day of June of that year the Brush, and the Laing, Wharton, and Down Companies gave notices for the Western and Central and the Eastern districts, respectively, and the ordinary statutory steps followed in due course. The Brush Company had, as stated, accepted the terms of the Commissioners' contract, and the Laing, Wharton and Down Company now decided to fall into line with them;† and in May, 1890, those contracts were sealed, and the Provisional Orders became law in that Session of Parliament.‡

Not until 1891 were a similar contract and Provisional Order granted to the Brush Company for the Western district. Thus, after nearly 13 years of deliberation on the subject, the scheme for supplying electricity to the City of London for public and private consumption became legally possible, and all the special powers which the Commissioners sought to obtain in the interests of their ratepayers had been secured.

* The contractors who tendered were the—
1. Central—Anglo-American Brush Corporation.
2. London—London Electric Supply Corporation.
3. West—Metropolitan Electric Supply Company.
4. All—House-to-House Electric Supply Company.
5. East—Messrs. Laing, Wharton and Down.

† The Commissioners had required Mr. Preece to report fully on the Thomson-Houston system of arc lighting as established at Sheffield and the St. Pancras station, as well as at Taunton.

‡ The names of Mr. E. Garcke and of Mr. Sydney Morse are so well known in connection with the industry, that it is appropriate to record here that to them is largely due the credit for carrying through final arrangements for these Orders, which were exceptionally intricate in their character.

Capital Expenditure.

The question of raising capital for electricity supply companies has not differed much in its conditions from other sister industries. This Paper would be less instructive if that part of the subject was overlooked, and it is noteworthy that, even with a field for the supply of electricity in which the gas company had a gross income of over £370,000.* Even in 1891 it was not thought prudent to do what is called "go to the public," in the first instance, with a plainly stated prospectus. Such a statement most certainly would have shown that the supply of electricity to the City should be an undertaking affording as sound an investment as could be found anywhere, and also one which at an early date, under the operation of the sliding scale already alluded to, would allow of the cost of the current being reduced below the maximum of 8d. As we all know, a very old way of commencing to raise capital has been brought out under a new name, namely, by the starting of a "pioneer company," which is one way of getting an instalment of capital together to make a beginning. Of course there is no engineering justification for it, but the financial physician has prescribed it, and hence this first capital must be spent with a primary object of showing that something can and will be done. The future of the undertaking from the structural point of view may become quite a secondary consideration, and, indeed, may be ignored if it interferes with the parade with which it is intended to "draw" the investing public. They—the public—have only themselves to thank if this sort of thing is necessary. Engineers and Contractors have no real interest in its existence.

The contracts with the Commissioners for the public lighting of the City were dated:—

For the Eastern district, May 28, 1890;
" Central " " 19, "
" Western " February 5, 1891;

and they required that the main thoroughfares should be completed with arc lamps in the Eastern and Central districts by February 28 and 19, 1892, respectively, and in the Western district by November 5, 1893. The "first sod was cut" on January 5, 1891, when a junction-box was constructed on the west side of the Mansion House, with an inscription inserted in the wall. The first street was lighted in July, 1891. The arc lighting generating plant was permanently fixed in the pioneer buildings, but in other respects the installations were designed to be temporary. The two Companies, namely, the Brush Electrical Engineering Company and the Laing, Wharton and Down Construction Syndicate, to whom, as has been stated, the Provisional Orders and contracts had been granted, had, in February, 1891, tranferred their interests, through an exploration company and an electric and general investment company, conditionally, to the City of London Pioneer Company, of which Company I was appointed the engineer after the contracts had been made. These interests included the obligation to complete the purchase of sites for generating stations—one at the Wool Quay, in Lower Thames-street, the other at Meredith's Wharf, in Bankside. Part of the consideration for the transfer of the responsibilities and liabilities of the "*concessionaire*" companies was in each case a provisional contract for the supply and erection of the entire plant and equipment of one temporary (or pioneer) and one permanent generating station for the supply of current to, and for the transforming of current in, each district. In similar cases the work of pioneer companies has been confined to the task of financing. Unfortunately—I think—in this case the City of London Pioneer Company had to undertake actual work, so far as the public lighting was concerned, because the time remaining—namely, about 12 months—in February, 1891, when the contracts for the Central and Eastern districts had to be completed, was even then very short. But these provisional contracts for temporary work included some private lighting;† the object being the old-fashioned one, to create a display—in my opinion—at the expense of good work, and with the risk of a legacy of trouble, anxiety, and failure. Suffice it to say that, in spite of every possible precaution to prevent it, no small part of this temporary work has had, or will have, to be moved or altered after having been put to work; and a large part of the money spent on these temporary installations—

* The day and night populations of the City, respectively 261,061 and 50,652 in 1881, had altered in 1891 to 301,384 and 37,694. The day population, as compared with towns and counties in England and Wales, is larger than 26 counties, and all other towns except Liverpool, Manchester, Birmingham, Leeds, and Sheffield. Before 1891 there were 3,136 public gas lamps, costing £10,530 per annum.

† The first current for private lighting was commenced on December 11, 1891, to the Mansion House, but it was more than six months after before the plant could be run during daylight hours.

Digitized by Google

amounting, together with other expenses, to a very considerable sum—must be more or less wasted.*

On July 13, 1891, while the pioneer contracts were still uncompleted, all the interests acquired by the pioneer company were taken over by the City of London Electric Light Company for a further consideration, by which means the lighting of the City was, with the consent of the Board of Trade and of the City authorities, amalgamated into one undertaking instead of three, and it was at last possible to begin work in earnest, with a hope that the words "temporary" and "provisional" were past.

The estimates for works upon which the capital of the new Company was raised amounted to—

Buildings	£53,000
Equipment of the three stations	493,250
Distribution	342,850
Total	£889,100

This was exclusive of the cost of the sites.

The contracts for public lighting with the "*concessionaire*" companies, which had been taken over from the pioneer company, besides providing for the supply and installation of the plant and equipment for one station for each district of the City, provided also the arc and glow lamps for the public lighting, with their fittings, exclusive of posts and lanterns, in every respect sufficient to enable the new City Company to fulfil the terms of the contracts with the Commissioners of Sewers, as follows :—

Eastern district. (Laing, Wharton and Down Company.)		Central district. (Brush Electrical Engineering Company.)		Western district.	
Arc.	Glow.	Arc.	Glow.	Arc.	Glow.
233	307	138	302	144	297

Total arc, 515. Total glow, 906.

Besides this, the contracts between the same parties required the work to be done for equipping the stations and providing the plant for the supply and conversion of current for private lighting to be in accordance with detailed specifications and schedules of prices. It was agreed that these details and prices were to be laid down afterwards and settled between the engineer of the Company and the contractors ; differences (if any) to be referred to Mr. Preece.

The contracts required that the output of the Brush stations for the supply of the Central and Western districts, and of the Laing, Wharton and Down Company's station for the Eastern district, should, including the pioneer plant, be as follows :—

——	Public and other arc lighting.	Private lighting.
	Kilowatts.	Kilowatts.
Eastern district	450	4,800
Central ,,	330	3,900
Western ,,	220	3,400
	1,000	12,100
		1,000
Total kilowatts	...	13,100

Adding together the cost of the contracts and estimates, and dividing by the total of 13,100, we obtain the following total cost per kilowatt :—

Preliminary expenses	£8,000
Work done by the pioneer company, including some work of distribution	46,000
Extras on ditto	10,000
Contracts for the stations	493,250
Estimate of cost of completing distribution	342,850
	900,100
Add 8 per cent. for the cost of the sites of the generating stations	72,008
Total	£972,108

Namely, total per kilowatt, nearly £75.

* I had been through such troubles in connection with electrical and other engineering too often not to throw all my weight into the scale against temporary work of any kind. It is only before an assembly of engineers that an engineer can hope to find any appreciation of such a situation. Neither financiers nor contractors sympathise with his efforts to prevent unnecessary expenditure, except so far as it affects their own interests. The financier does not mind so long as the total expenditure is within his estimates of what the investor will stand ; and the contractor need only care if he is going to accept any payment in shares, and not always then. Besides this, there is the long series of harassing engineering consequences arising out of crude, hasty, and ill-considered work preliminary to a great undertaking. Many of us have been through it, and learnt to take it as part of the day's work ; but, all the same, it is always regrettable.

Anyone present will realise that the preparation of detailed specifications for the equipment of an electric light supply station, both for generating and transforming, requires the fullest technical description. Besides that of the boilers, engines,* and dynamos, there are the questions of the arrangements for transport and conveyance of coal and refuse, economising, condensing, and stoking ; there are also the details of foundations, drains, subways, travellers, lifts, cranes, and the lighting of the station, as well as telephonic communication with, and equipment of, transforming substations. I need not say that the preparation and agreement as to the details of specifications, after a contract is made and the total price to be paid is fixed, is a somewhat novel task for the engineer of the spending company. In this case the putting of the cart (as it were) before the horse fortunately did not end in miscarriage. The engineers on both sides † were anxious, while doing justice to their employers, to arrive at a fair and reasonable solution, and Mr. Preece could tell you that it ended in only about half-a-dozen points of difference between them and me having to be referred to him, in specifications containing nearly 120 pages of closely-printed matter.

In these specifications, although the specialities of the two contracting firms were well known, nothing was laid down to confine them to their own particular make of engines, boilers, dynamos, transformers, and lamps. The contractors described to me the sizes of the units they desired to employ. They are not limited to any particular form of driving, and, as far as possible to produce uniformity, the speeds and electrical conditions which they desire to use are allowed. Economising, automatic stoking, and condensing, and all possible accessories—including testing and switchroom apparatus and fittings—are required of capacity equal to the full output of the plant. All the conditions of the different stages of generating are rigorously prescribed so far as the results under test are concerned. For instance, it is laid down in the specifications that, after providing for all extraneous steam consumption and waste, the standard of consumption of coal, including the steam used in the condensing pumps, shall not exceed 5lbs. for the high-tension alternating currents, and 7lbs. for the high-tension continuous currents, per Board of Trade unit delivered at the terminals of the primary mains in the stations. Amongst the extraneous uses of steam to be excluded from the above basis are included that used for the power expended in moving water, coal, and refuse. The tests to prove this are adapted to the circumstances of running the station‡—a matter, as most of us know, not always easy. Therefore their nature and number are to be subject to the approval of the engineer, so as not to clash with the conditions of statutory supply from the station. The tests of each unit estimated to have an output of 400 kilowatts, or of each group of units with an output of 1,200 kilowatts, are necessarily dependent on the circumstances of the load on the station. The alternating plant—both Brush and Thomson-Houston—was experimental at the time the contracts were made, therefore the first examples had to be under trial for six months. These trials had to be coincident with the supply, and dependent on the load on the station, and the contractors for that period were to be responsible for failure of all kinds. Under strict penalties, the contractors are answerable for the dimensions of foundations, flues, and chimneys, and are required to guarantee absence of vibration, noise, and smoke nuisance.

As regards the boiler tests, under the usual conditions of temperature, external and at the base of the chimney, and state of barometer, and with coal having a calorific value of 13,500, it is obligatory that 77 per cent. of the heat is transferred to the water by the boilers and economisers together. As regards the consumption per horse-power of steam in the engines, the Brush Company have agreed to a limit with full load of 22lb. of steam exhausting to the atmosphere, and 18lb. when condensing. The Laing, Wharton, and Down Company have agreed to a limit of 20 and 17 respectively. For the commercial efficiency of the electrical 400-kilowatt generators, 80 per cent. when working at full load is prescribed, 2 per cent. of that only being allowed to be absorbed in the excitation. Besides, there was given a description of every test which each portion of the plant would be required to

* Prof. S. P. Thompson's opinion, in November, 1891, on the types of engines which the contractors, under the restrictions and definitions contained in the specification, proposed to adopt, was that. while expressing his own opinion on the advantages of triple expansion, and of engines of the closed type, he confirmed entirely the conditions that the choice should be of the vertical and direct-coupled type ; he postponed his final opinion until six months' running of the first group of 400 kilowatt units had been completed. It is to be hoped that he will be able now, more than two years having passed, to give electrical engineers his further experience in the subject.

† Mr. Raworth and Prof. Kennedy, assisted by Mr. Wharton, represented the two contracting companies, while I represented the City of London Electric Lighting Company.

‡ The contractors could not provide means of running their large dynamos at their works. All real tests had to be made after delivery. This was an inherent difficulty for the engineer.

Digitized by Google

sustain. At the same time, the widest latitude as regards *design*, throughout the whole of the station plant and accessories, is allowed.*

I do not know if the meeting considers if any better way could be adopted for protecting the expenditure of capital and stimulating the energies of contractors, after it had been decided by others how much should be spent, how much should be the maximum output of the plant, and who were to be the contractors.

(To be continued.)

* The essence of these specifications was that, except in respect to a few points not within the scope of the contractors' work as electrical engineers, all details of design were left to them, subject to the final approval of the engineer.

LEGAL INTELLIGENCE.

Alabaster and others v. Harness and others.

This case came yesterday before a Divisional Court of Queen's Bench, consisting of Mr. Justices Mathew and Collins, on appeal from the Master and Judge in Chambers, who held that the defendants' objection to answer interrogatories administered to him was a good objection on the ground that it would tend to incriminate him. The plaintiffs' (the appellants) contention was that it was not a good objection, and that the defendants ought to answer. Mr. Bankes, who appeared as counsel for the appellants, said the action was brought by the proprietors of the *Electrical Review* against Mr. Harness and the Medical Battery Company (Limited) to recover damages for maintaining an action which was brought by Dr. Tibbits against them. The interrogatory the plaintiffs sought to have answered was with reference to the communications which passed between defendants and Dr. Tibbits, and the payments made, or promised to be made, with reference to the action of Tibbits *v.* the Proprietors of the *Electrical Review*. The defence was that the offence of maintenance was indictable at common law. Mr. F. Dodd, who appeared for the respondents, contended that they were not bound to answer the interrogatory. Their Lordships dismissed the appeal, and directed that the costs should be the defendants (the respondents) in any event.

Edison-Bell Phonograph Corporation (Limited) v. Smith and another.

Mr. Justice Wright, on Thursday last week, delivered judgment in this case, which has been briefly reported in *The Electrician*. The learned Judge said this was an action for an injunction and damages in respect of infringement by the defendants, G. Albert Smith and J. Lewis Young, of a patent, numbered 19,153, and dated July 15, 1890, taken out by Mr. Edison, and by him assigned to the plaintiff company. The defence was a denial of the validity of the patent on the ground of want of novelty and of utility. The patent was in respect of improvements in connection with the phonograph. It was claimed by the defence that for some years the Graphophone Company had been advancing on similar lines to the present patent in the perfecting of phonographs. In the early history of the invention there had been a single diaphragm, and the defendants in their machines merely carried out this idea. The defendants' contention was that claim 1 of Mr. Edison's specification was for a bald idea, and was, therefore, bad; and that, if any of the claims were upset, in the absence of disclaimer of the invalid claim, the whole patent was bad; and, further, that, with the exception of claims 2 and 4, all the plaintiffs' claims were bad. The learned Judge, having stated the course of invention before the date of the patent in question, said that the then existing defects might be summed up as being that the parts of the phonograph were too numerous, and, the minutest accuracy of adjustment being essential, this had to be obtained and continually renewed by skilful manipulation of several parts frequently applied, and requiring judgment in order to ascertain that each working part was precisely in its proper relation to every other. The inventions made by Mr. Edison in 1889 disclosed in the plaintiffs' patent reduced the number of separate parts, and tended to produce automatically and with mechanical certainty, accuracy, and rapidity effects which previously depended on personal judgment and nicety of manipulation. The foundation of the improvement was the discovery that the floating weight which had been thought applicable only to the reproducing point was sufficient to regulate also the recording point. This made it possible to return to the system of using a single diaphragm under conditions which made it no longer a single diaphragm, but two diaphragms combined into one and carrying both the recording and the reproducing point, and means were devised by which such an arrangement became effective, either of the two points being brought to bear at will in the same line. This was the substance of the invention, though the plaintiffs seek to protect also certain improvements in details. The first claim was attacked for being too wide and general and for want of novelty; the third, fifth, sixth, seventh, and eighth on the ground of want of novelty and utility. Even if Mr. Edison's evidence stood alone he (the learned Judge) could see no reason to doubt that each of the details contributed something important, though minute, and was novel in its application to the phonograph, and was the result of prolonged study and experiment by a person of the highest mechanical genius. Each contributed to the machine becoming automatically accurate and rapid, and was adopted in the machines sold by the defendants. Each of them (except, perhaps, the seventh and eighth) appeared to be claimed only in combination with the principal invention, and if that was new and useful and properly described the patent was not, in point of law, invalidated by the addition of a claim for a further combination with the good invention of something which is not new or not useful, and which is not claimed except in that combination, because such an addition does not widen the patent or debar the public from the free use of the old or useless matter except when in combination with the principal invention. There remained the question whether the patent is invalidated by the first claim. That claim appeared to him to be on the face of it a claim of monopoly for every form of phonograph in which the two styles are attached to one diaphragm, so that either style can be brought to bear on the cylinder. It was a claim for a particular arrangement of essential parts of a machine, as disclosed in the specification. The claim was for a monopoly of that arrangement when carried out by any means substantially similar to those in the specification. He was, therefore, of opinion that there was both novelty and utility in the use of a single diaphragm carrying the two different points in such a way that either can be brought to bear, and there would, consequently be judgment for the plaintiffs.

Keith, Prowse and Co. v. the National Telephone Company (Limited).

This was a case tried before Mr. Justice Kekewich, and was of importance to persons hiring the use of telephone wires and apparatus. It was a motion by the plaintiffs for an interim injunction to restrain the defendant company from cutting, disconnecting, removing, or otherwise interfering with any wire which, on December 30, 1893, was used or connected for use as a private wire, or an exchange wire, for telephonic communication for the purposes of the plaintiffs' business. The plaintiffs originally (October, 1889) rented a private wire from the defendant company under an agreement, by which the plaintiffs agreed to pay £11 per annum for each wire, payable quarterly, the first quarter ending September 30, 1889, and each subsequent payment to be made on the corresponding day in each quarter, the agreement to terminate at the end of three years. The agreement stipulated that it should be subject to all proper wayleaves, permissions for attachments, poles, and other easements, being obtained and retained by the company; and the renters covenanted to give every facility in their power in the way of poles, attachments, &c., for running their own wire, and also those of other subscribers to the company's system, whether exchange or private. The agreement expired by effluxion of time in June, 1892, but the parties went on by mutual consent as before, the rent being continued to be paid on the same quarter-days, but no fresh agreement in writing was entered into. On the 29th December last, the plaintiffs gave notice to the company to terminate the existing arrangement or tenancy at the expiration of six months from "December 31, 1893." In reply, the company sent the plaintiffs notice, dated Saturday, "December 30, 1893," terminating the existing agreement "forthwith," and demanding rent up to "31st inst.," and informing the plaintiffs that they (the company) would on Monday morning, January 1st, proceed to disconnect the wires and remove the instruments. Thereupon the plaintiffs on the same day, December 30th, paid the rent demanded, and at once applied for and obtained from the Vacation Judge an *ex parte* injunction restraining the threatened proceedings until over the first day of the present sittings. The main question was whether the ordinary law of landlord and tenant could be applied to a hiring of telephone wires under such circumstances as in the present case so as to require from the Company as "landlords" either a six months' notice of determination if it is a yearly hiring, or a three months' notice if a quarterly hiring. The plaintiffs contended that the relation of landlord and tenant subsisted between the parties, and that the plaintiffs held the use of the wires and apparatus on a yearly or at least a quarterly tenancy, which could only be determined on due notice, and that the acceptance by the defendant company of rent for December 31, 1893—that is, a day after the notice determining the tenancy—constituted a waiver of that notice. The defendant company, however, contended that what the plaintiffs were really seeking was specific performance of an alleged contract; but that the contract was not one of which the Court would order specific performance, since it could not see to the electric batteries being kept filled, and so forth; also that the analogy of "landlord and tenant" was misleading. In the present case the contract was nothing more than a contract to supply certain chattels, a supply of electric current, and the services of workmen to keep up that supply; and, therefore, the meaning of the arrangement was simply that it should continue only so long as was convenient to both parties.

In delivering judgment, his LORDSHIP said he should only deal with two points—first, Was this a case in which the Court should grant an injunction if the plaintiffs made out an equity other than that for specific performance, it being impossible for the Court to compel complete specific performance in a case of this kind? Here there was no question of erecting apparatus; the only question was as to maintenance. It appeared to him that the difficulty of supervising the maintenance of apparatus ought not to prevent the Court from interfering with the cutting of the telephone wires and the removal of the instruments. An analogy might be suggested in the case of an agreement for the tenancy of manufacturing premises, the lessor providing steam or motive power set up in some neighbouring building, and then, in breach of the agreement, threatening to cut off the power. The Court would say that that he could not do; the agreement was to let the premises with the power, and cutting off the power would be a breach of the agreement. Then came another question, whether the action of the defendant company had rendered it impossible for them to say that the agreement was at an end. There was some argument as to whether this case could be regarded as a case of "landlord and tenant," and it was said that the plaintiffs, and not the defendant company, were really the "landlords" because, it was urged

the plaintiffs were grantors of an easement to the defendants to set up poles and apparatus on their, the plaintiffs', property. In his opinion that was not the case. The company erected these poles and apparatus; they belonged to them, and though the case was not that of landlord and tenant of real property, still there was a hire agreement, and the plaintiffs, who were to have the enjoyment, were described as "renters." His Lordship thought that the position of landlord and tenant as regarded these chattels was established. Then, upon this agreement, his Lordship assumed for the present purpose that under clause 8 the company might determine the agreement by notice "forthwith." They determined it "forthwith" on Dec. 30, 1893. At the same time the company demanded rent up to "December 31st"; the amount was paid and accepted as "rent." The result was that the company demanded and received rent for a day beyond the time of the determination of the agreement. It was not competent for them to affirm and disaffirm in that way; and, according to the law of landlord and tenant, they must be regarded as having waived or abandoned their equity. In his opinion the company had no power to say that the agreement was determined on December 30th, for they had received rent for the 31st, and therefore the plaintiffs were tenants, having the right to use the apparatus for that day. The original agreement was for three years from July 1, 1889, and therefore would come to a conclusion on June 30, 1892. From that time forward the plaintiffs continued to use the apparatus without any new agreement, and the rent was paid according to the old agreement. The result was that there was a holding-over upon the terms of the old agreement. He did not mean to decide that point; but, as his decision on the preceding point might be regarded as implying that now the company might intervene and say "We determine the tenancy to-day, and we will take care not to ask for rent beyond to-day," he would say that that question was not argued sufficiently before him to enable him to pronounce a decision on the point; but his present impression was that the receipt of rent after June 30, 1892, and the continued occupation by the plaintiffs, constituted a tenancy from year to year. He did not think that the company ought now to interfere without the question being submitted to judicial decision. He should, therefore, grant an injunction restraining the company from interfering with the private wires pursuant to the notice they had given. The injunction would continue until the trial of the action or further order, and the costs of the motion must be costs in the action. The injunction would extend only to the private wires, and not to the exchange wires, which were not in question.

CORRESPONDENCE.

PERSONAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I saw with much surprise an announcement in your current issue that I am about to leave England. I wonder it has not occurred to you that, before publishing a statement which, if erroneous, may injure my professional relations in this country, it would be proper for you to make quite sure your information is correct; and this you could have easily done by inquiry at my office.

I cordially dislike the importation of personal matters into a scientific paper; but as your statement is calculated to alienate my present and possible future clients, I would ask you to allow me to make the following corrections:—

(*a*) My leaving England shortly is not even in contemplation.

(*b*) My leaving it at a future date (which will give me ample time to finish all the work I have in hand) is in contemplation, but is by no means certain.

(*c*) I have been offered an important appointment in Germany, and am in negotiation about it; but the matter is still pending, and will not be settled either way for about a month. Whether I shall leave England or not I do not even know myself at present, so that your statement was certainly premature and may, perhaps, also turn out to have been incorrect.—Yours, &c., GISBERT KAPP.

31, Parliament-street, Westminster,
February 10, 1894.

[We received the information in a very detailed form from a source which, we understood at the time, was authorised by Mr. Kapp himself. We greatly regret the possibility that the premature publication should be in any way likely to injure Mr. Kapp's professional relations in this country.—ED. *E.*]

IS THE HIRE WORTHY OF THE LABOURER?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should much like to call your attention, and that of interested readers, to a subject which must be extremely important to many electrical engineers, especially the younger generation.

The principal electric stations employ men who are variously termed "superintendents" and "electricians-in-charge." Their duty consists of taking sole responsible charge of the running of the station for a certain number of hours every day, usually eight. During this time they are "in command" of the station, and every accident or mishap has to be set right, and accounted for, by them. Naturally, therefore, they comprise in themselves the duties of the men under them; that is to say, they must have had practical experience of driving, stoking, &c., and in emergencies may have to carry out those duties. Added to this they must have had a sound theoretical training, as well as some workshop experience.

Yet, in a great many stations, they get paid lower salaries even than the stokers. If they have to work overtime, which happens fairly often, they do it with the privilege of receiving nothing for their trouble. In a great many cases the electrician's pay is a third less than the driver's. Can this be just or reasonable?

I well understand the electric lighting company's desire to keep down working cost, but surely the shoe should not be pinched at this point. At any rate they ought to afford to pay as much for electricians as for drivers. The cause of this state of things is, in a great measure, to be looked for in "over supply," and in the presence of young men well supplied with money, who will take a post for a mere song, in consideration of experience gained.

If the companies have not sufficient justice to pay their electricians better, and to enable them to live moderately on their pay, the electricians must find a remedy. I prefer conciliatory measures, but if these fail, "union is strength."

Trusting to your kindness to insert this note, and hoping some readers will write in support of my statements.—Yours, &c., SUPERINTENDENT.

DOUBLE-ACTING GAS ENGINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the remarks I made on the driving of alternators by gas engines, in your issue of December 22nd last, I did not refer by name to any maker of engines, nor did I refer to any particular installation. I thought it best to treat the subject impersonally, and on general grounds, but Mr. Hartley, on behalf of Messrs. Dick, Kerr and Co., now challenges me to come to closer quarters with reference to double-acting engines, and I beg you will allow me to make the following observations.

I referred to a double-acting Otto engine, and not to the obsolete Griffin engine, which has a six-stroke cycle and a scavenging charge of air, which helps to cool the cylinder and piston. It is said that Messrs. Dick, Kerr and Co. have "turned out hundreds of double-acting engines," and I accept the statement; but it refers to engines of the Griffin type, and has little bearing on the working of the double-acting Otto engine which has been introduced recently. In the latter the explosions are more frequent, and there is no scavenging.

Mr. Hartley admits that an engine of this type requires "two admission valves, two exhaust valves, and two ignition valves," whereas a single-acting engine requires one of each. He argues, however, that it is no worse to have a set of valves at each end of a gas engine cylinder than at each end of a steam engine. To this I would say that it is common knowledge that the valves of a gas engine are not only more numerous, but are more difficult to keep in order than those of a steam engine; and this being so, I cannot help feeling that from a practical point of view it is wrong to nearly double them in number. The steam engine gives troubles of its own; but in a gas engine the frequent corrosion of the exhaust valve, the cleaning of the ignition valve, and the renewal of the ignition tube, are troubles from which the steam engine is free. All these defects Mr. Hartley thinks it right to double.

I have not said that a double-acting gas engine is wrong in principle—I do not think so—but I do say that the double-acting Otto engine now made is not as good as a single-acting engine for practical purposes.

I have not measured the consumption of oil or water; but I was told by the attendant of an engine which has been

Digitized by Google

working a few months that it consumed more oil and more water than an ordinary gas engine of the same power. I also know that there was trouble about the water supply for cooling the engine, although there was a circulating pump. The extra cost of oil or water cannot, however, be serious; but there remains the awkward fact that if a double-acting engine needs more cooling, as I believe it does, there must be an equivalent loss of heat and a consequent additional loss in efficiency.—Yours, &c., J. EMERSON DOWSON.

February 12, 1894.

DRIVING ALTERNATORS BY GAS ENGINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have only to-day noted an article by Mr. J. E. Dowson in your issue of December 22nd, or I should have commented thereon earlier. The author remarks, "*It is tolerably certain that double-acting gas engines as they are now constructed, will not be used to a large extent, and for practical purposes we need only consider the well-known single-acting engines.*" Had Mr. Dowson said, "*Single-acting gas engines will not be used to any large extent and we need only consider double-acting engines,*" he would have shown a clearer understanding of the wants of electrical engineers.

No matter what the system of electrical distribution may be, an engine with four impulses per two revolutions is a far more satisfactory motor than an engine with only one impulse and three waste strokes. Yet how can this greater number of impulses be obtained in single-acting cylinders, with the Otto cycle, without excessive cost, complication and clumsiness? Two double-acting cylinders give exactly what is wanted in a neat and effective way.

Gas engines driven by generator gas give such economical results, that the extensive adoption of this power for electric lighting is only a question of time. Gas engine manufacturers, who wish to come in for their share of this work, should turn their attention to the development of double-acting engines.

Messrs. Dick, Kerr and Co. recently built for me an engine of 100 H.P., which is now working a small alternating current central station at Rugby with Dowson's gas. In this engine, I had two double-acting cylinders placed one behind the other, the two pistons being connected by a rod coming out of the front of one cylinder and entering the back of the other, the front piston rod driving on to a connecting rod in the ordinary way. Thus, in this engine, there are two impulses per revolution, with only one connecting rod, one crank, and only two main bearings. All the parts in front of the cylinders are exceedingly simple, and need be of no larger size than for a 25-H.P. engine of the ordinary type. The blow of the explosion is only equal to that of an ordinary engine of one quarter the power.

This tandem double-acting engine does not, as Mr. Dowson says, take more oil than other engines of the same power. More cooling water may be required, but this I doubt. Even if it is so, it does not matter, for the tanks are arranged so that this water is used again and again.

I anticipated trouble with the piston rods, but there is no more trouble with these than in a steam engine. This engine is by far the most perfect one yet devised for electric lighting work *of all descriptions*, even for direct-current systems using accumulators. The starting is effected by using one cylinder as a steam engine, with steam from the gas generator boiler, until the engine gets explosions in the other cylinder. This simple and efficient starter could not be used in a single-cylinder single-acting engine. In all, except certain details, the above-mentioned tandem double-acting engine has given great satisfaction. I have had troubles, but these are all in a fair way to be overcome. I do not like the arrangement of connecting the two ends of the cylinders so that one gas valve supplies both ends. It would be more satisfactory that the four explosion chambers should be independent of one another, and act practically as four separate engines. The Rugby engine will shortly be altered in this respect.

I do not believe that engines of this type will yet work alternators in parallel *satisfactorily*, but if parallel running becomes possible, it will be effected far more easily by double-acting cylinders than by any arrangement of single-acting engines. For *satisfactory* parallel running, it is necessary that there should be a continuous turning effort, and this means that governing must be done, even with a four-impulse engine, by controlling the power of the impulses and not by cutting out. To arrange this is difficult. We tried a valve gear at Rugby for effecting this, but it was, in my opinion, too complicated for general use, and it was therefore removed. The engine is now governed by cutting out either one, two, or three of its impulses, as necessitated by the load. Even at the *lightest* load the engine gets one impulse per two revolutions, which is as much as a single cylinder single-acting engine gets at *full* load. I am a consistent advocate of parallel running in alternating central stations, but, convenient as this method of working is, I would sacrifice it rather than lose the great advantages of using cheap gas power. Parallel running might be effected by some arrangement by which the alternators could be coupled mechanically, but this would probably only be satisfactory on a small scale.

Another advantage that the double-acting engine has, is that it can always be made of twice the power of single-acting engines. For driving large dynamos direct, a most compact plant can be made by using two double-acting cylinders placed side by side vertically, as in marine engines. I believe that this is the form that the large central station gas engine of the future will take.

I apologise for trespassing so far on your space, but I have recently had a good opportunity of continuously testing a large double-acting engine, and I think my experience may be of value to your readers.—Yours, &c.,

21, Carlton-hill, N.W. J. A. MCMULLEN, M.I.E.E.

ELECTRIC WAVES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The publication of an English translation of the late Prof. Heinrich Hertz's Papers on the propagation of electric action through space cannot fail to give a great impetus to the study of electric and magnetic phenomena in this country, and will, no doubt, give rise to much discussion. Without in the least desiring to underrate the value of these Papers, and whilst recognising to the full the epoch-making nature of Prof. Hertz's work, it is impossible not to feel, after reading "Electric Waves," that our ideas of even fundamental matters are still very far from being clear. The particular point which struck me when reading the work was the care the author takes when arranging his experiments to distinguish between electric and magnetic effects, and the seemingly inadequate manner in which these two effects are treated in the fundamental considerations upon which he bases his equations. Indeed, electric waves, magnetic waves, and electromagnetic waves would seem to be used by Hertz and others as synonomous expressions.

At the instance of Lord Kelvin, the title of the German work, "Untersuchungen über die Ausbreitung der elektrischen Kraft," was changed in the English translation to "Electric Waves." That such a title should have been selected is interesting. Indeed, to a limited extent, it seems to be in conflict with the author's, and, I may even say, with the generally held theoretical views.

Speaking of the electric and magnetic forces Hertz* says, "Starting from rest, the interior of all bodies, including the free ether, can experience disturbances which we denote as electrical, and others which we denote as magnetic. The nature of these changes of state we do not know, but only the phenomena which their presence causes. Regarding these latter as known, we can, with their aid, determine the geometrical relations of the changes of state themselves. The disturbances of the electric and the magnetic kind are so connected with one another that disturbances of the one kind can continuously exist independently of those of the other kind; but that, on the other hand, it is not possible for disturbances of either of the two kinds to experience temporary fluctuations without exciting simultaneously disturbances of the other kind." Now the statement that although electric and magnetic fields may "continuously exist independently," they cannot "experience temporary

* "Electric Waves," p. 197.

Digitized by Google

fluctuations without exciting simultaneously disturbances of the other kind" must surely mean that electric and magnetic waves cannot exist independently, that radiant energy must be electro-magnetic. Numerous other passages might be quoted, some of which would lead one to think that pure magnetic waves can exist, and others that pure electric waves also can. One passage of Lord Kelvin's I will venture to quote from the preface: *"The title alone of the other Paper, 'On the Energy lost by Radiation from Alternating Currents,' is in itself a valuable lesson in the electromagnetic theory of light, or the undulatory theory of magnetic disturbance." Are we to regard this as indicating Lord Kelvin's opinion that pure magnetic waves may exist, but that light waves are electro-magnetic ?

In a letter to *Nature*, Prof. Simon Newcomb† makes some suggestions concerning the nomenclature of radiant energy, and remarks, "The nomenclature of the subject has come down from a time when it was supposed that there were three distinct kinds of rays in the spectrum, severally known as light, heat, and actinic rays." . . . "I cannot but think that the general understanding and application of the now received theory of the subject, which recognises in this form of energy no differences of kind except wave length, has been materially retarded by the want of a corresponding nomenclature." Now even if electric waves and magnetic waves cannot exist separately, the one kind may be so powerful that the effects of the other kind are almost negligible. Referring to his experiments on this subject Hertz ‡ says: "As required by theory, the mechanical effects of the electric and of the magnetic force prove to be, in general, of the same order of magnitude; the preponderance of the one over the other in each particular case is mainly determined by the proportions of the neighbouring parts of the ring and of the fixed conductors. The more these approximate to the state of infinitely thin wires, the more the magnetic force comes into prominence; the broader the surfaces which are attached to them, the more is the magnetic force overpowered by the electric force." As a matter of fact, the mathematician must recognise differences of kind as well as of degree, though no doubt such a course will add very materially to his difficulties. On this point Lord Kelvin§ seems even to go further, for not only must we distinguish between magnetic and electric fields, but also between resinous and vitreous electricity and north and south polarity. He says: "Fifty years ago it became strongly impressed on my mind that the difference of quality between vitreous and resinous electricity, conventionally called positive and negative, essentially ignored as it is in the mathematical theories of electricity and magnetism, with which I was then much occupied (and in the whole science of magnetic waves, as we have it), must be studied if we are to learn anything of the nature of electricity and its place among the properties of matter." Hertz‖ also remarks, after giving his fundamental equations, "I wish to point out once more that I only attach value to the theory of electromagnetic forces in moving bodies here proposed from the point of view of systematic arrangement. The theory shows how we can treat completely the electromagnetic phenomena in moving bodies, under certain restrictions which we arbitrarily impose. It is scarcely probable that these restrictions correspond to the actual facts of the case. The correct theory should rather distinguish between the conditions of the ether at every point and those of the embedded matter. But it seems to me that, in order to propound a theory in accordance with this view at present, we should require to make more numerous and arbitrary hypotheses than those of the theory here set forth." The time has clearly scarcely arrived when the nomenclature of the science can with safety be based upon theoretical considerations.

It seems, therefore, that we know of at least two kinds of transverse wave energy; but whether, when the lengths of both kinds of waves are sufficiently short, they are both capable of producing visible rays, or whether light results from one only, can only be cleared up by experiment. To quote Hertz* again, "The details of the experiments further prove that the particular manner in which the electric force is propagated exhibits the closest analogy with the propagation of light; indeed, that it corresponds almost completely with it. The hypothesis that light is an electrical phenomena is thus made highly probable. To give a strict proof of this hypothesis would logically require experiments on light itself." Here light is regarded as an electrical phenomena, not an electromagnetic one. It seems as though to the words electric and magnetic specific and generic meanings are indifferently attached.—Yours, &c., R. M. Deeley.

SUPPLY COMPANIES AND COOKING APPLIANCES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In *The Electrician* of last week, under the head of Trade Notices, you refer to the efforts of the Gas Light and Coke Company to increase their business by further advertising the uses of gas for cooking and heating purposes. You add that you are surprised that the makers of electrical heating and cooking appliances do not follow the same course, so that the public may know where to obtain them. In this we think you have confounded the Gas Light and Coke Company, who are a supply company, with manufacturers. We think that the Gas Light and Coke Company are right, and that it is the duty of supply companies to inform all users of their current that electric cooking apparatus is now satisfactory, and cooking by electricity can be carried out at a reasonable cost. We have suggested this course to some of them, but have received the reply that they do not care to mention manufacturers' names; whereas the Gas Light and Coke Company in their circulars give the names of five firms whose appliances are recommended for use.

It is very evident that so soon as electric supply companies have satisfied the demand for lighting they will have to turn their attention to utilising their supply during daylight hours. Why should they delay any longer in this matter. It is so evident that increasing the day load will tend to reduce the total cost of the production that nothing need be said on this point.

It is only fair to say that some of the supply companies, notably the City of London Electric Supply Company, are beginning to see this, and to this last Company we have recently supplied a number of large ovens. We believe they intend to let them out to some of their customers, and we also believe that other companies are proposing to follow the same course.—Yours, &c., Crompton and Co. (Limited).

THE MILEAGE OF THE SUBMARINE CABLES OF THE WORLD.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The following discrepancy in the total mileage of the submarine cables of the world seems to be worth while drawing your attention to.

In his Presidential Address before the Institution of Electrical Engineers, January 26th, 1893, Mr. Preece gives the total length of the submarine cables of the world as 139,571 miles. *The Electrician* Electrical Trades' Directory for 1894 gives 153,649 as the total mileage, presumably up to the end of 1893. During 1893 4,767 miles of submarine cable were laid. The total mileage, therefore, to the end of 1892 was 148,882.

The difference between this figure and that of Mr. Preece amounts to no less than 9,288 N.M., which surely calls for some explanation.—Yours, &c., R. C.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1894 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now ready. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

Tenders Invited.—The Vestry of St. Mary, Islington, invite tenders for the supply and erection of the necessary plant and machinery required for the supply of electric current within the parish, and also tenders for supplying the conduits and mains which are to be laid by the Vestry. The specification is divided into 10 sections, and contractors may tender for the whole or any one or more sections. Specifications, conditions, &c., may be obtained of Mr. Albert Gay, Vestry Hall, Upper-street, London, N., on and after the 19th inst.; and tenders must be sent in to Mr. W. F. Dewey, Vestry Clerk, at the Vestry Hall, not later than noon on Wednesday, March 21st. Further particulars will be found in our advertisement columns.

——— The Vestry of St. Pancras invite tenders for (1) Lancashire boilers, economisers, feed pumps, &c.; (2) engines, dynamos, condensing plant, &c., for their electricity and refuse destructor station in King's-road. Drawings may be inspected and specifications, &c., obtained from Prof. Henry Robinson, C.E., 13, Victoria-street, London, S.W.; and tenders must reach Mr. Albert E. Pycraft, the chief clerk, at the Vestry Hall, Pancras-road, London, N.W., by noon on March 5th. Some further particulars appear in our advertisement columns.

——— The Town Commissioners of Ballymena require tenders for lighting the town, either by gas or electricity, from August 16, 1894, until May 16, 1895. Specifications, &c., may be obtained from the Town Clerk, to whom tenders are to be sent by March 3rd.

Tenders Accepted.—The Corporation of Darwen have accepted the tender of Mr. T. Barton, of Blackburn, for a complete generating and distributing plant to be used at present for the lighting of the new technical schools, but which, we understand, is intended to form a nucleus plant for the lighting of the town. The plant and apparatus includes Barton dynamos, switch and distributing boards, Siemens' cables, E.P.S. storage batteries, and Stockport gas engine.

——— The tender of Messrs. S. J. Waring & Sons, of Liverpool, has been accepted by the Clerks' Cafe Company, Limited, for the electric wiring and the ventilating of the Cafe Hamilton, Chapel-st, Liverpool, for the sum of £320.

——— The Wolverhampton Town Council have accepted the tender of the Bedford Engineering Company, Bedford, for the supply of an overhead travelling crane at the Corporation's electric lighting works in Commercial-road, for the sum of £187. 10s.

Sale by Auction. — Our advertisement columns contain an announcement of the sale by auction, by Mr. William Lamb, at St. Helens, Lancashire, on Tuesday, the 27th inst., of Abell's Electrical Engineering Works, Raglan-street, St. Helens. The property comprises the buildings, with an "Otto" gas-engine, various machine and other tools, stock of electrical appliances, &c., the whole forming a complete manufactory, with plant and stock ready for immediate work. Further particulars may be obtained of the auctioneer, or of Messrs. Barrow and Cook, solicitors, St. Helens.

Appointment.—The Great North of Scotland Railway Company have decided to attach an electric light department to their existing telegraph department, and we understand that extensive plant and apparatus will shortly be put down. Mr. L. Le Gros Horne (of the electric light department, G.P.O., London) has been appointed to the post of superintendent of telegraphs and electric light to the Great North of Scotland Company.

Bankruptcy.—Mr. Moses Humm, electrician, 8, Westbourne-road, Forest Hill, Kent, has been adjudicated a bankrupt, and the first meeting of creditors will be held at 24, Railway-approach, London Bridge, on February 21st, at 11:30, and the public examination at the Greenwich County Court on February 27th, at 1 o'clock.

Liquidations.—A petition for the compulsory winding up of Latimer Clark, Muirhead and Co. (Limited) has been presented by Messrs. Willans and Robinson (Limited), and is down for hearing at the Royal Courts of Justice on the 21st inst.

Liquidations.—The secretary to the Richmond Electric Lighting Company has issued a circular in which he states that the debenture holders of the Company having taken action and obtained the appointment by Mr. Justice North of Mr. James Worley as Receiver and manager of the property and business, it is impossible for the Company to pay the debts as they fall due, and the shareholders have therefore passed a resolution for liquidation, and Mr. Worley has been appointed liquidator.

——— The creditors of Messrs. Latimer Clark, Muirhead and Co. (Limited) are required to send their names and addresses and the particulars of their debts or claims to Mr. James Worley, of 27, Leadenhall-street, London, E.C., the liquidator. The full text of the notice will be found in our advertisement columns.

——— At meetings of the Orient Electric Light Company (Limited), held on December 7th and 29th, it was resolved to voluntarily wind up the Company, Mr. Robert Wolfenden, of 43, Finsbury-square, E.C., being appointed liquidator. The Company was registered on November 29, 1887, with a capital of £5,000, divided into 20 shares of £250 each, to carry on in India, Burmah, Ceylon, and elsewhere, the business of an electric light, heat, and power supply, and a telegraph and telephone company in all or any of its branches. At the time of making up the last return (December, 1891), 13 shares were taken up, and calls of £100 paid on each had been made.

Re J. and W. Weems.—In this bankruptcy Mr. J. Gourlay, C.A., trustee, announces the payment of a first dividend of 2s. in the £, payable on and after Thursday, March 29th next, at 24, George-square, Glasgow.

New Russo-German Tariffs.—Under the Commercial Treaty recently concluded between the crowned heads of Russia and Germany, and which is to come before the German Reichstag for confirmation in due course, a rearrangement has been made in several groups of manufactures in which our readers are interested, more particularly as, under the "most favoured nation clause," Great Britain participates in any modification of international tariffs. The proposed Russo-German tariff on telegraph wires of all kinds is reduced from 4 to 2 gold roubles; on dynamos of all kinds from 4.80 to 4.32 gold roubles; on gas, air, or petroleum engines, from 1.70 to 1.40 gold roubles—these latter rates applying to all machinery not specially rated. The tariffs on technical apparatus are reduced from 8 to 6 gold roubles. Other articles upon which the tariffs have been reduced are iron or steel wire covered with thread or gutta-percha, from 9 to 2.20 gold roubles; and chloride of zinc, from 1 to .80 gold roubles. A reduction from 8 to 6 roubles per pood is made in the duty on driving belts for machinery (unsewn). The gold rouble is taken at 3s. 1½d., and the pood is 36lbs. avoirdupois.

Telegraphic Addresses.—We have received a copy of "Sell's Directory of Registered Telegraphic Addresses." This work, the outcome of Mr. Sell's efforts to obtain recognition from the Post Office for his work in the compilation of registered telegraphic addresses, is now issued, and forms a bulky volume of more than 1,000 pages, in addition to a useful gazetteer of the United Kingdom, and some general information usually to be found in such compilations. The list is compiled under the direct authority of the Postmaster-General, and forms a first issue under these auspices, but is the eighth annual publication of Mr. Sell's book. It is unfortunate that Mr. Sell should consider it necessary to warn the public against using telegraphic addresses given in other publications; there is nothing whatever to prevent others than Mr. Sell compiling a list of telegraphic addresses of equal authenticity to his own, although due credit may still be awarded to Mr. Sell for his courage in overcoming the obstinacy of the postal authorities, and bringing together the list under review.

Messrs. Pyke, Harris and Co.—This firm forward us illustrated sheets of several of their specialities.

The Boudreaux Dynamo Brush Company.—We understand that this brush, which was fully described in *The Electrician* a year ago, is being extensively used in France, Belgium, Germany, and other parts of the Continent, and the rapidly increasing sale proves the favour in which it is held. It is claimed that the conductivity is much greater than that of similar gauze brushes, because, being made of very thin sheet, they are more solid.

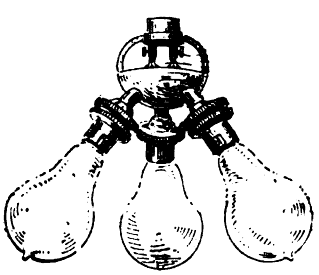
Messrs. Mather and Platt, Limited.—The London branch of this firm has just completed an extensive installation of the electric light at the residence of Mr. R. C. Christie, near Sunningdale, Surrey. The generating plant includes a 12-I.H.P. vertical boiler and engine driving a No. 4 Manchester dynamo, and a two-barrel slow-speed pump for supplying an overhead tank from a well in the engine-house. A set of 54 Chloride Company's cells are included. Nearly 100 lamps are used, and the plant provides for the supply of light to several outbuildings.

Messrs. T. and W. Ide.—Mr. William Ide has retired from the well-known firm of Messrs. T. and W. Ide, glass benders and merchants, of Ratcliff, London, E., and Mr. John Ide has been

Digitized by Google

admitted a partner in the firm, which will be carried on under the same name.

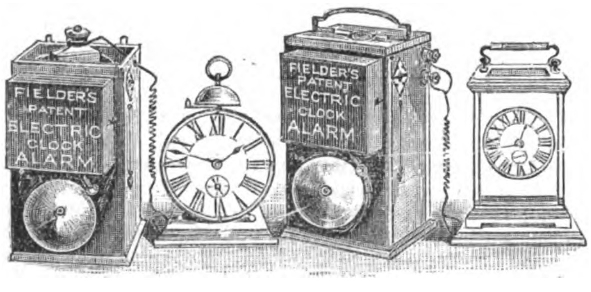
MESSRS. VERITY AND SONS' CATALOGUE.—We have received from Messrs. Verity and Sons a copy of their new catalogue, devoted to the display of the large variety of electric light fittings and accessories manufactured by them, which are here illustrated in endless profusion. The catalogue contains more than 300 large, well-filled quarto pages, throughout which illustrations, particulars, and prices appear of brackets, standards, electroliers, pendants, shades, reflectors, and, in fact, artistic and all kinds of electric and combination fittings are shown, many of which, although of most elaborate design, are manufactured and sold at very low prices. It is impossible, with such an immense range of choice, to particularly specify designs of more than usual merit, or to do justice in the limited space at our command to such a work; but we can safely recommend architects, electric light contractors, dealers in electric fittings, and all concerned or interested in the installation of the electric light to consult the bulky volume issued by Messrs. Verity and Sons, where, if anywhere, their requirements must



Verity's Improved Detachable Ball Body for 2, 3, 4, and 5-light Combinations.

surely be catered for. The book comprises 21 sections, commencing with plain and inexpensive brackets, and ending with electrical etceteras. Included in this latter section is an illustration of an improved detachable ball body, to fit an ordinary bayonet lamp-holder, and adaptable for two, three, four, or five lights off the same holder. Some time back, in these columns, we referred to the handiness of such an arrangement, and are pleased to find that Messrs. Verity have considered it worth their while to include it in this list. A single-light pendant is converted into one with two or more lights without disconnecting any of the wires, but by simply removing the lamp and inserting the plug at the top of the body into the ordinary bayonet lamp holder, the body can be instantly detached to allow of the shade to be removed for cleaning. A patent is applied for for this device, which we think will be in considerable demand for ball-room and other festive purposes. On page 237 a very useful brass deck fitting is shown, with a 3-light combination enclosed. Another section of the book in which several excellent examples of Messrs. Verity's special branch of work is well represented is Section VI. (Ceiling Fittings). The book is well printed throughout, in a variety of colours, setting off the various sections to the best advantage; it contains over 1,000 illustrations, and weighs 3½ lbs.

ELECTRIC CLOCK ALARMS.—Mr. Walter Fielder, of Shakespeare-road, S.E., is introducing a new patent electric clock alarum of a very simple character. The illustration below shows the combination applied to either a circular or square clock. By a simple



contrivance at the back of the small stand, the winding key, is placed in a metal slot, and upon the hands on the dial reaching the set time, contact is made automatically, and the alarum rings until the person for whom the call is intended removes the plug, when the ringing ceases. The clock is not fastened to the stand, nor is it in any way connected with the electric current, and can, in fact, be placed in any part of the house, so long as the electric circuit is completed. The stand and battery case is made in walnut wood, and the whole can be obtained with a circular clock for 15s. 6d., or with a square carriage clock for £1. 1s. Mr. Fielder is himself the sole patentee and manufacturer of the combination, although several wholesale houses are taking up its sale. There should be no difficulty in creating a considerable demand for this useful domestic appointment. It should be added that the electrical portion can be used as an ordinary electric bell, the metal contact plate forming a push, and, of course, the clock can be used quite independently of the electrical part of the apparatus.

NEW WORKS.—Messrs. Baird, Thompson and Co., engineers, have lately acquired the large freehold property known as the Charlton Engineering Works, Islington, London, N., together with the adjoining property and the machinery and plant contained therein. The works are being entirely overhauled and fitted with the latest improvements in labour-saving appliances, &c. The buildings are to be lighted throughout with the electric light.

MESSRS. MAVOR AND COULSON.—We have received a copy of the latest edition of the catalogue of plant, issued by this firm. The catalogue is entitled "Electric Light and Power," is well bound, and contains a considerable amount of practical information which should be useful to electrical engineers and to intending users of electric current. The illustrations are numerous and well executed; they represent the various dynamos, motors, regulators, lamps, &c., made and supplied by the firm.

NEW BOOKS AND NEW EDITIONS.—Messrs. Whittaker and Co. announce a second revised edition of Mr. Bowen Cooke's work on "British Locomotives," and a new work on "Surveying and Surveying Instruments," by Mr. G. A. Middleton. This firm will also shortly issue the second volume of Sir David Salomon's "Electric Light Installations," and the third and concluding volume is now in the press.

SMOKING CONCERT.—The staff of the City of London Electric Lighting Company will hold a smoking concert at the London Tavern, Fenchurch-st, London, E.C., to night (Friday) at 7.30 p.m., under the chairmanship of Col. H. C. Seddon.

ABERDEEN.—The Governors of Robert Gordon's College have considered the report presented by the City Electrical Engineer on the question of the electric light in the College premises. A committee appointed to consider the subject has reported that it is desirable to extend the lighting to the whole of the College buildings, and that, as the present plant is unsatisfactory, the proposals of the electrical engineer, that a re-wiring be effected, and the currents taken from the Town Council's mains, has been adopted.

ABERGAVENNY.—Power has been granted to the Improvement Committee of the Local Board to engage the services of an expert to advise them in the matter of lighting the district by electricity.

ACTON.—The Local Board have, on the advice of the Finance Committee, instructed their Surveyor to make inquiries as to the cost of installing a system of electric fire alarms throughout the Acton district.

AYR.—At the Town Council meeting on Monday it was stated that the initial cost for introducing the electric light into Ayr was between £16,000 and £18,000. It has been agreed to appoint an electrical engineer to survey the burgh and to report on the most advantageous method of electric lighting by steam-power, and to furnish estimates of the probable expense of the whole scheme, which are expected to confirm the above figures.

BANDON (IRELAND).—The local electric lighting company have decided to take no further steps in applying for a Provisional Order for the lighting of Bandon by electricity during the present year, and this being the case the Local Board have also decided to take no further action in the matter for the present.

BLACKPOOL.—At the last meeting of the Town Council a proposal from the Electric Light and Tramways Committee that the Local Government Board be asked permission for the Council to borrow £24,000 for electric lighting plant and extensions (repayable in thirty years), came up for discussion; and Councillor Pearson, in moving a confirming resolution, said it was his pleasurable duty to present a favourable report on the electric lighting scheme, and he therefore asked for permission to extend the station, so that they could supply the demands already made upon it. They had over-spent on the estimate of their last borrowing powers between £3,000 and £4,000, and they propose to expend immediately in extensions a further £15,000, and for future extensions £5,000, making in all £24,000. The excessive expenditure was accounted for by the fact that the Committee had found it necessary to take into their own hands the meters and transformers, instead of permitting purchasers to put down their own. They had this apparatus now in stock in sufficient numbers to serve them for some time to come. They had also decided upon more artistic arc light pillars for a certain portion of the area, which cost £15 in place of the £7 originally estimated. This latter alteration had received the Council's approval. They had sought the advice of Mr. R. Hammond as their electrical engineer in all matters. There had been a considerable increase in the consumption of the electric current, and a decrease in the cost of production, which must ultimately benefit the borough. In October last it cost them £72 to produce 3,107 units, as against £41 in December for 3,119 units, showing a

Digitized by Google

greater production for a less cost, and at the end of the year they were producing current at 3d. per unit. The demand was much in excess of their present plant. For their extensions they would require extra engines of 500 H.P., and orders in hand—even without any order from the Tower Company—would require at least another set of plant. He estimated that they would be able to supply twice the amount of current now produced at a cost of about 2d. per unit for the extra output. Several amendments were produced, but ultimately the Committee's proposals were adopted by a large majority. Mr. Holroyd Smith's terms for estimates of cost and supervision of the works in connection with the placing in repair of the Corporation's electric tramways were also approved.

Bristol.—Energetic efforts are being made to convince the Bristol Corporation that the inhabitants of St. George are in earnest in their demand for the electric tramway. A large provisional committee is being formed in order to concentrate public opinion on the subject, in which the inhabitants of the district feel very strongly. Complaint is made that hitherto the important district of St. George has been isolated from Bristol, owing to the absence of communication.

Church Lighting.—The parish church of Leamington is now lighted by electricity. A 24-light electrolier is suspended from the dome, and an ornamental 10-light pendant is fixed to the roof of the sanctuary. The nave, transept, side aisles, and choir stalls are lighted by bracket lamps. Altogether there are 120 16-c.p., and about 70 25-c.p. lamps. The work has been designed by Mr. F. W. E. Jones, of the Midland Electric Light Company, the fittings being supplied by Messrs. Glover and Co., of Warwick.

Club Lighting.—The Committee of the Manchester Reform Club, in their report for the past year, state that the introduction of the electric light had occupied the Committee's attention for some years past, and during the past year it had been decided to proceed with the matter. The work had been entrusted to Messrs. Verity and Sons, who completed the installation in October last, at a cost of about £600.——The Committee of the Junior Reform Club, Liverpool, have called a meeting of the members to discuss the advisability of introducing the electric light. A report has been prepared.

Derby.—The Local Government Board have finally sanctioned the borrowing by the Corporation of £30,000 for electric light purposes, and £1,600 for land upon which the central station is to be erected. The Electric Lighting Committee's report has been submitted, in which it is recommended that Mr. J. E. Stewart be appointed engineer and manager of the electric lighting works, at a salary of £260 per annum, and Mr. A. P. F. Moore as assistant engineer, at a salary of £109. 4s. per annum. The Committee have now completed their staff appointments, and will commence operations when the works are formally taken over on the certificate of Messrs. Bramwell and Harris. The report was adopted.

Dover.—It has been decided to instal the electric light in the Connaught Hall, and an estimate has been received and accepted from the Brush Company for the necessary work, fittings, &c., for the sum of £572. 12s. The lighting of the Maison Diew Hall (estimate cost, £330) has been deferred.

Drogheda.—The offices and yards of the Drogheda Steam Packet Company have been lighted by the electric light, which is voted a great improvement upon the old gas lighting.

Edinburgh.—A considerable extension of the electric lighting at the new Caledonian Station, Princes-street, has just been completed. The whole of the completed platform and offices are now lighted by electricity, and seven 2,000-c.p. arcs have been erected in the shunting and goods yard, in addition to about 400 16-c.p. incandescents provided for the goods sheds, offices, and signal boxes. Gas has been entirely dispensed with.

Harrogate.—A public meeting was held at the Town Hall last week to consider the expediency of the Corporation undertaking the installation of electric light for the public lighting of the borough, for which they had already obtained power. The Corporation recently decided to put down a refuse destructor in conjunction with the electric lighting plant, but upon this additional scheme difference of opinion has arisen amongst the members of the Corporation. A resolution was proposed at the meeting, asking the Corporation to reconsider the question with the view of transmitting their rights to a private company, but an amendment was proposed, calling upon the Council to themselves take up the question of developing the electric light in the Borough. The meeting, however, was against this course, and decided by a large majority in favour of the original resolution.——At the meeting of the Corporation the decision come to at the above town's meeting was discussed, and it was pointed out that many other improvements had been effected in the town in spite of public meetings carrying resolutions against such improvements. After the discussion the recommendation of the Electric Lighting Committee that the Council itself carry out the electric lighting order, was carried.

Harrow.—The Local Government Board have intimated to the Harrow Local Board that a public inquiry will be held at the Local Board offices as soon as arrangements can be made, in reference to the application for an electric light Provisional Order and other local matters.

Liverpool.—An important inquiry has been held by the Local Government Board as to whether the time has come when the important districts of Toxteth Park, Walton, West Derby, and Wavertree should be incorporated with the City of Liverpool. The advantages of this incorporation were pointed out by the leading members of the Corporation, and particular attention was drawn to the fact that whereas West Derby, which is larger in area than Liverpool itself, has hitherto strongly opposed the incorporation, it now comes forward with a proposal that it would be for the general good that such incorporation should take place. So far as the scheme of incorporation affects the Liverpool Electric Supply Company, a friendly agreement has, we understand, been arrived at to extend the purchasing clause of the Company's Order so as to enable the Corporation to give notice of their intention to purchase the Company's undertaking in the year 1900, instead of in the year 1897 as under the original arrangement.

Limehouse.—The Electric Committee of the Board of Works have prepared a report, which was to have been presented at the last meeting, but owing to additional information coming to hand at the last moment, the report has been deferred until the next meeting of the Board.

London County Council.—The Finance Committee have recommended, and the Council have approved, the loan of £9,000 to the Islington Vestry towards the purchasing of a site for the central lighting station; and the loan of £29,700 to the Vestry of St. Pancras towards the cost of electric lighting works, the loan to be for a period of 25 years. Some discussion took place upon the St. Pancras loan, the Vestry contending that they should be allowed a longer period than that based upon the life of the work, in order that they might have equal advantages with an independent electric light company, which does not have to pay off its capital. The Council, on the contrary, were of opinion that although the contentions of the Vestry were admitted, it should be remembered that a private company was not able to borrow money at 3½ per cent. as the Vestry could, and that the Company would be compelled to establish a reserve fund to meet depreciation and other contingencies, including that of a possibility of being bought up by the local authority. A motion approving of the contention of the St. Pancras Vestry was subsequently lost. The Council have also had under their consideration a considerable extension of the Metropolitan Fire Brigade, and contemplate the expenditure of about £100,000. We understand the Council have under consideration the advisability of adding to the number of street fire alarm posts, which have proved so useful in the past.

Londonderry.—The Corporation have had an exhaustive debate upon their electric lighting scheme, which has met with every possible opposition from the gas interests. A discussion of 2½ hours' duration was mainly taken up by petty squabbling over purely personal matters, which certainly reflects but little credit upon the Councillors as business men. It appears that the original estimates have been somewhat exceeded, and this has been made the occasion for a perfect tirade of abuse against the chairman of the Electric Lighting Committee, the electrical engineer, Mr. Blake, and other prominent officials of the Corporation. So highly does party feeling run in Derry on this question that the *Sentinel* (which is the mouthpiece of the opponents of electric lighting) devotes nearly five columns to this miserable wordy war. After a considerable waste of time a resolution was moved by Mr. Councillor Hastings as follows:—"That, having considered the position of the electric lighting scheme, and that as 170 lamp pillars are already erected and cables laid thereto, the Council authorise the borrowing of sufficient money to complete 170 arc lamps, and leave the same in proper working order; and that no further electric lighting of the city, either public or private, be undertaken by this Corporation without the careful consideration and consent of the Council." In discussing this resolution, and in reply to a question, Mr. Councillor Magee, the chairman of the Electric Lighting Committee, stated that the number of lamps in their present contract was sufficient for the efficient lighting of the city, but the citizens had been getting used to luxuries, and required more light, hence the increase in expenditure over and above the original estimates. After agreeing to insert the words "not to exceed £5,000," Mr. Hastings' resolution was agreed to.

Margam.—At the monthly meeting of the Local Board the Lighting Committee recommended that the district be lit by electricity, and that Messrs. Drake and Gorham be authorised to prepare a report on the subject.

Manchester.—At the last meeting of the Council exception was taken by Mr. Alderman Leech to the arrangement proposed to be entered into between the National Telephone Company and the

Digitized by Google

Council with regard to the laying down of telephone wires. The National Company has undertaken to place their wires underground, at their own expense, to the satisfaction and with the approval of the Corporation; to pay for the opening of the streets and further repair; and to pay the Corporation a yearly rental. It was this arrangement to which exception was taken, the point of the objection being that the Corporation were breaking away from their connection with the Municipal Corporations' Association. Four speakers pointed out that the recommendation of the General Purposes Committee to accept the arrangement with the National Company was one which would benefit Manchester, and should be entered into regardless of any connection between the Corporation and the Association. A discussion ensued, in which the Lord Mayor strongly supported the arrangement with the National Company, and this was agreed to by a large majority. It is proposed that the terms of the agreement shall be embodied and scheduled with the Act of Parliament which the Corporation is now promoting.

MISSENDEN (BUCKS).—The Vestry have entered into an agreement with an electric light company to light the streets of the village during the winter months This is the first district in the county that has adopted the electric light for street illumination, although the Wycombe Town Council occasionally "discuss" the subject.

NEWCASTLE-ON-TYNE.—An offer has been made to the Corporation by one of the electric lighting companies serving Newcastle to light Grainger-street, one of the principal thoroughfares, with electricity at the same cost as for gas. The City Lighting Committee have decided to obtain fuller details before accepting.

NEWPORT.—In a letter dated February 6th, Messrs. Crompton and Co. (Limited) repeat an offer made by them on the 27th ult., to the Town Council, viz., to lay down a low-pressure plant for the sum of £19,500, and to work the same for a term of years at about one-half the cost of that estimated for a high-pressure system, the plant supplying a larger area than that contemplated in the specification. Messrs. Crompton and Co. are also prepared, if required, to supply and work a high-pressure plant. A meeting of the Local Gas Company was held on Tuesday, and the subject of the possibility of early competition with the electric light was mentioned. It was suggested that the greatest care should be taken that the illuminative power of the gas was kept up to the highest possible standard, and it is likely the Gas Company may shortly announce a reduction in the price of their commodity. The Parliamentary and Improvement Committee have finally considered the question of the electric lighting tenders, and find, on exhaustive consideration, that the difference between Messrs. Crompton & Co.'s tender and the combined tender of Messrs. Fowler & Co., and Messrs. Siemens Bros. & Co., is £1,913. The Committee visited Messrs. Crompton's works, at Chelmsford, and were invited to consider the advantages of the low-tension system. After careful consideration, however, they adhered to the high-tension system, and recommended that the all-round tender of Messrs. John Fowler and Co. (Leeds), Limited for the whole installation (except the cables), at £19,797, be accepted, subject to such variations as may be required, and that the tender of Messrs. Siemens Bros. and Co., for cables, at £2,896, be accepted on condition that these cables are made in England. At the meeting of the Council, at which the report of the Committee was presented, a resolution was proposed that Messrs. Fowler and Co.'s tender be declined, and that the tender of the Uskside Engineering Company to supply the engines be accepted, and Messrs. Crompton and Co. be granted the balance of the contract on the basis of the amount of their original tender, and on condition that they consent to give to Newport firms the making of any machinery, tubes, or other work that could be done in Newport on equal terms. Councillor Wilkinson, who proposed this amendment, objected to more than £2,000 being needlessly sacrificed, and submitted a memorial from the Engineers' Society, the Steam Engineers' Society, and the Iron Founders' Society, urging the acceptance of Messrs. Crompton and Co.'s tender on the conditions stated in his amendment. After adequate discussion, the Committee's recommendations were adopted, the voting showing 5 for the amendment, 20 against, and 10 neutral.

OSWESTRY.—An attempt to bring about a satisfactory arrangement between the Town Council and the electric lighting company was made at the last meeting of the Council but without effect.

PADDINGTON.—The Guardians have appointed a special committee to consider and advise upon a proposal to light the workhouse infirmary by electricity.

ROTHESAY.—The Harbour Trust has appointed a committee to report as to the practicability of introducing the electric light at the harbour.

SOUTHPORT.—It was recently proposed to introduce the electric light into the new infirmary, and at a meeting of the Board of Guardians the subject has been discussed, but the final decision has been left for a future meeting.

SOUTH WALES INSTITUTE OF ENGINEERS.—In reference to a paragraph which appeared in our issue of January 19th, we are requested to state that the electric light installation was not put down by Messrs. Verity and Sons as there stated, this firm having only supplied the fittings to instructions.

STAFFORD.—At the meeting of the Town Council last week the Electric Lighting Committee reported that their engineer, Mr. Bell, had had several interviews with Dr. John Hopkinson on the subject of their electric lighting scheme, and that the necessary plans, drawings, and specifications were ready for obtaining tenders for buildings, plant, &c. The Committee recommend that tenders be obtained for electric lighting machinery and other necessary works, and Mr. Alderman Peach, who proposed the adoption of the Committee's report, stated that considerable progress had been made towards carrying out the powers of the Provisional Order of 1890, inasmuch as the sanction of the Local Government Board had been obtained to the loan of £20,000 (as stated in our last issue), and drawings of the proposed central station were now submitted. Under the Committee's plan the new works had been so designed that the whole could be duplicated without alteration or demolition. Included in the plant proposed to be put in were three Lancashire boilers, which would supply the gas works with steam as well as the electricity works, and room would be provided for additional boiler capacity. Dr. Hopkinson's recommendation was that three horizontal compound high-pressure steam engines should be put in, each of 100 H.P., and the space so arranged that two additional 200-H P. engines could afterwards be added. Included in Dr. Hopkinson's recommendations is an accumulator set of 112 cells. The station's capacity is to be arranged for 5,000 16-c.p. lamps before extensions are required. The Committee estimate that the capital required will necessitate an annual payment of £790, and that the estimated annual working expenses, including repairs and maintenance, would amount to £1,250 per annum. The accounts of the Gas and Electric Light Committee were to be kept strictly separate and distinct. The Committee's report was adopted without discussion.

ST. IVES.—In reply to a letter from Messrs. Baily, Grundy and Barrett, the Town Clerk has been instructed to state that the Council have no opposition to offer to a private company lighting the town by electricity.

STIRLING.—The Board of Trade having informed the Stirling Town Council that, in order to place themselves in a legal position in opposing the application of the Caledonian Electric Supply Company for a Provisional Order, the Council must itself apply for such Order, a special meeting of the Town Council is to be held to consider the letter from the Board of Trade, which has taken the Councillors by surprise.

WARMINSTER.—A 2,000-c.p. Brockie-Pell arc lamp has been placed over a new memorial fountain in the market place at Warminster, current for the lamp being obtained from the lighting installation of Mr. M. Hill at the Station Saw Mills. After a provisional trial, three additional lamps are to be erected, by which means the whole market place will be lighted electrically.

WEST HARTLEPOOL.—The Town Council have discussed a resolution approving of the erection of the overhead system of electric traction, on condition that poles be erected on one side of the thoroughfares only. Ultimately, after some discussion, the matter was again referred back to the Committee which has the matter under consideration for further report. It has further been proposed that application be made by the Council to the Board of Trade to grant the Council a Provisional Order to supply electricity within the district. This matter has also been referred back to the Property and Lighting Committee for further report.

COMPANIES' MEETINGS AND REPORTS.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The seventh ordinary general meeting of this Company was held on Thursday at 1, Great George-street, Westminster, Mr. Granville R. Ryder presiding.

The SECRETARY (Mr. R. S. Erskine) read the notice calling the meeting.

The CHAIRMAN said: It is gratifying to us, after working away at this Company several years to find ourselves able to present to you what is in all respects a satisfactory report, and not only satisfactory so far as it shows that we are able to give you a further one per cent. dividend, but also in the prospect which it gives us of the future. With regard to the figures, I think the increases in them are encouraging. Of course, as a basis of comparison, it is necessary to keep back the new district and confine ourselves entirely to the old district, the new one only having come in for a broken period of the year, I find that we have increased the number of houses and shops connected

Digitized by Google

with the system from 550 in 1892 to 650 in 1893. With regard to the 8 c.p. lamps we have increased the number from 47,441 to 59,267, an augmatation of 11,826. After deducting from the 724,308 units of electricity sold in 1893 the 28,600 required for the new district, we have a total of 695,708 units for the old district as against 535,343 for the year 1892. That is an increase of 160,365. The satisfactory thing about this increase of one-third in the electricity supplied, is that it was obtained at an increased cost of only about one-sixteenth. The gross earnings, less rebates, for 1892 were £16,628, whereas for 1893 they amounted to £20,746, an increase of £4,117 in the twelve months. Now, it is especially gratifying to find that the profit on that increase has been over 50 per cent. That is to say, the additional profit has sprung from £6,828 to £9,049, an increase of £2,221 on the enhanced gross earnings of £4,117. It might be alleged that we have reached the limits of expansion in our district. As a matter of fact, I consider we have done little more than touch the fringe of the business which we may look to obtain in future years. If you take Prince's Gate, Rutland Gate, Ennismore Gardens, Exhibition-road, and other roads of a like character in the neighbourhood, all inhabited by better-class people, I think you will agree with me that they will all eventually have the electric light. I feel strongly that the electric light is the light of the future, and there must come a time when all the superior houses will avail themselves of it. Then there are large flats being built in different parts of the estate, and large houses are being converted into flats, which are good customers of ours. It is no doubt thought by many that the time would come when we must reduce our price. When that time arrives I cannot say that I shall fear the result very much, because with a reduction in price will come a great increase of business, and with it a cheaper output of electricity. Therefore I think there will be a considerable compensation for any loss in price by increased business and the reduction in the cost of supplying the electricity. With regard to the capital account, which we do our best to put down, I may say that in a company like ours it is impossible to altogether close it. During the past year it has increased by £19,860, being made up of £7,260 of the Five per Cent. Second Preference and £12,600 of the Four and a-Half per Cent. Mortgage Debentures. That increase of capital has been spent on the purchase of the freehold of one of our stations, the purchase of the new district from the Chelsea Company, on laying additional mains, &c. The next point to which I wish to refer is the writing down of the renewal account. What we feel is, that while we are increasing our profits we should try and write down to the largest extent we can, in fairness to the present shareholders. We have written off against preliminary expenses and the cost of the debenture issue about £379, thus reducing that amount to £500, and we have written off law suspense account £779, and in other ways we have made provision for depreciation and renewals, amounting in the aggregate to £2,456, which I think is a considerable sum for one year. It is impossible to say very much about the new district for the short time we have been working it. Its gross revenue for the half year we have have had it has been £953. I cannot say how much of that is net profit, but I shall look for from 9 to 10 per cent. in future upon the outlay. Upon the whole, I think the accounts are satisfactory, and point to a prosperous future. I will now move the adoption of the report and accounts.

Sir FREDERICK J. BRAMWELL, Bart., F.R.S., seconded the motion.

Mr. HEDGES inquired if they had reduced their price for electricity since last year?

The CHAIRMAN replied that they had, in the way of making a considerable rebate to their large consumers.

The resolution was then agreed to unanimously.

The CHAIRMAN then moved the declaration of a final dividend, making 5 per cent. for the year, on the Ordinary shares.

Mr. G. H. HOPKINSON seconded the motion, which was carried.

On the motion of Mr. J. F. ALBRIGHT, seconded by Mr. HEDGES, a sum of £500 was voted to the Directors for their services during the past year.

The retiring Directors, Mr. R. W. Wallace and Mr. A. S. Bolton, were re-elected, and Messrs. Lovelock, H. W. Whiffen, and Dickinson were re-appointed auditors.

A vote of thanks to the Chairman brought the proceedings to a close.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The thirtieth ordinary general meeting of this Company was held on Thursday, at Cannon-street Hotel, Mr. S. Wm. Silver (Chairman) presiding.

The SECRETARY (Mr. W. J. Tyler) read the notice convening the meeting.

The CHAIRMAN said: I presume you will take the report as read. Now, I think when we last met I held out favourable prospects for the year which has recently closed. Since then, we have had that much-to-be-deplored stoppage of the collieries. That has interfered with our operations to a certain extent, exercising an effect upon our working expenses. I think I may here mention that the steamer which returned from laying the cable on the West Coast of South America, brought back several hundred tons of coal, which have been found useful in our works. It is rather a remarkable thing that we in England should be importing coal from the West Coast of South America. The effect of the stoppage was felt by industrial concerns such as this. The stoppage of mills, I need not say, reduced the quantity of material required for engineering purposes. At the time of our last meeting I certainly did not look upon our general sales as the sheet anchor that they have proved to be. We have fallen back upon them, as you will have discovered from the report. We have done little in submarine telegraph work. We have had a contract to fit up the City of Brussels with the electric light, and to the credit of Mr. William Gray (the youngest son of our managing director), and Mr. Russell, who was associated with him in the undertaking, it has proved a complete success. Well now all this means that more capital is required, looking at the way in which our money is invested in works, in stock, and in other respects. Hence, in the best interests of the shareholders, and to put us in a position to purchase on the most favourable terms, we have determined to recommend the placing of a further sum to reserve. I cannot help referring to the stagnation of trade, which has enhanced the competition we experience and increased our difficulties in doing good business. There is plenty of business to be done, but the difficulty is to select that which is not likely to prove unprofitable in any way, and I must say that the greatest care and caution have been exercised by all in connection with this concern. It affords me very much pleasure to recommend the adoption of the report, which, under the circumstances, as I have in a very few words pointed out to you, is to be looked upon as of a satisfactory character. I will, therefore, move:—

"*That the report and accounts now presented be received and adopted and that a dividend of 5 per cent., and a bonus of 2½ per cent., free of incom tax, which, with the interim dividend of 5 per cent. already paid, equals 12½ per cent. for the year, be now declared.*"

Mr. ABRAHAM SCOTT seconded the resolution, and added that the trade for the past year had turned out better than he expected would have been the case.

General TREVOR said he wished for some additional information with regard to the reserve fund, which stood at nearly half a million sterling, namely £450,000. That was a very respectable sum, and one of which they might all well be proud. If a bad year should come, in which no profits were earned, the debenture holders would have to be paid their full 4½ per cent., and even the Ordinary shareholders would expect something with such a handsome reserve fund. What he wanted to ask, therefore, was whether the Directors could dip into it. Was the £450,000 liquid and of a tangible character and invested in Consols, or safe Government and Colonial securities? If the whole sum was in their business it would be very difficult without crippling their operations to take any of it. That some of it was invested was clear because the accounts showed that they had debentures and shares in other companies to the extent of £207,042. He would also like to know whether that was the value of those debentures and shares now, or whether the figures represented the prices they originally paid for them? They might be worth more at the present time, or possibly less. Of course, the reserve fund was required for other purposes besides equalising the dividend in bad years, and paying the debenture interest. He imagined, however, that no portion of it was needed for maintenance of steamers, as there appeared in the accounts a separate item for that of £10,000. Before the accounts were passed he hoped the Chairman would tell them the nature of the reserve fund, and whether it could be drawn upon at once, if necessary, and it would depend upon the Chairman's answer whether he made any motion.

Mr. LAMONT remarked that he could understand it might be necessary at times to receive payment in shares of other companies, but he thought that, as a matter of principle, it was not advisable that one company should hold a large amount of shares in other companies. Of course, if the Chairman said it was necessary for the successful carrying on of the business, he had nothing further to say on the point. He also shared the curiosity of the last speaker as to whether the value of these debentures and shares, as given in the accounts, was their cost price or what they stood at on December 31st last.

The CHAIRMAN, in reply, said, I think General Trevor has studied the accounts pretty closely, but he has scarcely carried his investigations far enough. You will see that our capital is employed in land, buildings, and machinery, and without our reserve I am afraid we should have very little to fall back upon as an industrial concern and instead of having 12½ per cent. to declare, I think if we got 1½ per cent. it would be about as much as they could pay. I put that plainly to you, as many gentlemen present are men of business, who will appreciate what I say. I think it would have been well if General Trevor had studied both sides of the accounts thoroughly. Mr. Lamont, I think, referred to certain investments which, in the course of business, are desirable. That is so, and they are such as we could realise if necessary.

Gen. TREVOR: Is the value given their present value?

The CHAIRMAN: Yes.

Gen. TREVOR: Not what we may have paid for them, more or less, when we bought them?

The CHAIRMAN: No; certainly not.

Gen. TREVOR: Do I understand that the whole of this £450,000 of reserve is in the business?

The CHAIRMAN: Actively engaged.

Gen. TREVOR: Then it is in point of fact additional capital, although not raised by debentures or shares?

The CHAIRMAN: Without interest.

General TREVOR: Of course, I fully understand that without that working capital of £450,000, upon which no interest has to be paid, the dividend would be smaller. That I understand perfectly, but the question is whether it should be called a reserve fund? It is not actually reserve unless you can dip into it.

The CHAIRMAN: That is the usual course, sir.

General TREVOR: You could dip into the £207,000 of debentures and shares if you wanted?

The CHAIRMAN: Certainly.

General TREVOR said that after the Chairman's explanation he had no motion to submit to the meeting.

The resolution was then carried unanimously.

The CHAIRMAN: The next resolution I have to place before you is one for the re-election of Mr. Scott and Mr. Henderson as directors. In moving that these friends remain on the board, I have pleasure in saying that they have proved of great value and importance to us. I am sorry to

Digitized by Google

say that Mr. Henderson is unavoidably absent, and therefore, if you will allow me, I will put the two names together.

The Hon. HENRY MARSHAM seconded the resolution, which was passed.

Mr. GEO. HANBURY then moved, and Dr. Small seconded, the re-election of Mr. J. F. Clarke as auditor at a fee of 30 guineas, which was agreed to.

The CHAIRMAN said he might mention that the gentleman they had been good enough to elect as auditor was a member of the firm of Turquand, Youngs and Co.

At the request of the meeting, the CHAIRMAN then called upon Mr. Matthew Gray (Managing Director) to give an account of his recent visit to the Continent on the Company's business.

Mr. GRAY said that in consequence of their having the contract for lighting the City of Brussels with the electric light, he visited that place, and was pleased to find that the work had been done very satisfactorily—in fact it was the best central station he had seen. The authorities at Brussels were satisfied, and he thought it was very probable that they would go in for an extension of the electric light to a considerable extent. After visiting Brussels he went to the Company's factories at Persan-Beaumont in France, where he found everything in first-rate order and fully employed. Their factory at Silvertown was also well maintained and busily occupied. The competition during the past year had been very keen and they had had to fight over and over again several battles, but they had managed, as the shareholders were aware, to make a little profit. All the stocks and the value of the works had been very carefully gone into for the past twenty years, and he could assure them everything was in a very healthy condition. They turned out a great variety of articles and a great many of each sort. For instance, they had 500 girls employed in making bicycle tyres alone. There were numerous other matters he could tell them about, but he thought it hardly worth while detaining them.

A vote of thanks to the Chairman and Directors, proposed by Mr. LAMONT, and seconded by Gen. TREVOR, terminated the proceedings.

Newcastle and District Electric Lighting Company (Limited).

The seventh ordinary general meeting of this Company was held on Monday at 57, Westgate-road, Newcastle-on-Tyne. Mr. J. D. Milburn, the Chairman, presided.

The CHAIRMAN, in moving the adoption of the report (which appeared in our last issue), said that during the year they had had an increase of nearly 100,000 units of electrical energy. That came partially from the North-Eastern Railway Company, at the station and other works, but also to a large extent from individual consumers. That was to be looked upon as very satisfactory, because the more work they got to do the more it consumed of their standing charges, and the more profit, up to a certain degree, it allowed them to make. They had been able to effect considerable economy in coal consumption. The drift to the river, and the condensing plant, introduced by Mr. Parsons, had been a very great success, although the cost had been greater than was anticipated. The difficulties of sinking and tunnelling down to the river were, of course, unknown quantities to begin with, and did not come out quite as they expected; but their highest hopes in the direction of economy were now being realised. They had gone into the question of the utilisation of the town refuse as fuel, and it was found possible, not only to do a good deal with the fuel, but also to set up a paper factory alongside the works. Mr. Parsons, who had gone into the matter thoroughly, pointed out, however, that, with duff coal at 3s. or 3s. 2d. per ton, very little economy could be got with anything of the kind. The fuel was all very well, it would burn, but it took a lot of labour to shovel it on to the fires; and if they could get their boilers singing away at full pressure with coal as low as 3s. 2d. per ton, they could hardly go into a question such as that. There was another matter which went into the question of cost. They would see in the Gas Company's report that the Directors said that the policy of reducing the price to 1s. 10d. per 1,000 cubic feet had not fulfilled the expectations they formed of it, and that they were going to put the price back again. It was calculated in electric lighting that 6d. per unit was equal to 5s. per 1,000ft. of gas. But the more they had opportunity and experience of knowing how the light was used the more they were convinced that a great deal of waste took place in electric lighting. Now that the new lamps had come in this had to a certain extent disappeared. They found that a consumer put in exactly double the size of a lamp he required, and then ran it to death, with the result that at the end of two or three months he got out of it only two-thirds or a half of the power of the lamp, but had to pay all the same for the big effulgence he ought to have had. A lamp cost about 3s. 9d., although lamps were made and sold in this country for 9d. and 1s.; but there was a question as to the legality of that. It would be found great economy, after using the lamps three months, to take them out and destroy them and put in fresh ones; and if people who had had 25 c.p. lamps would remove them and replace them by 16 c.p. lamps, they would probably find no difference in the light, and pay very much less. Even an 8-c.p. lamp would give a very good light indeed. Great saving might be effected in this way, and he felt that they were approaching the day when the cost of the electric light would assimilate itself with that of gas. There was the question of the reduction of their own price, but they did not feel quite yet that they could recommend it; they had had no complaints. Gradually their customers were waking up to the better use and idea of the economy of the electric light, and they hoped that that would popularise the idea of the light. They had recommended the same dividend as last year. Probably they might have done a little more, but they felt that they might some year have drawbacks, and they might have some bad luck; and it was only right that they should be prepared for that. The feeling of the Directors was that they should not go backwards. If they got 6 per cent. this year, it would not be pleasant for the shareholders to go back to 5½ or 5 per cent. another year. They had applied to the Local Stock Exchange for a quotation, with the result that very shortly the shares would be quoted in the local list, and anybody who wished to buy or sell shares would have every facility for doing so.

A SHAREHOLDER asked if it were correct that the Corporation intended to have their own central electric lighting station, and, if so, would not that mean serious competition?

The CHAIRMAN said that the Company had made special agreements with the Corporation both with regard to the cost of street lighting and also in regard to the limitation of dividend, so that if the Corporation were attempting what was suggested, they would have a great amount of opposition to meet.

Sir BENJAMIN BROWNE seconded the adoption of the report, which was unanimously carried.

Mr. J. D. Milburn and the Hon. C. A. Parsons, the retiring Directors, were re-elected, and Messrs. Strachan and Co. were reappointed auditors, after which, a vote of thanks to the Chairman concluded the meeting. An extraordinary meeting was then held, when the Articles of Association were so altered as to allow the shares to be quoted in the local lists.

Liverpool Overhead Railway Company.

The ordinary half-yearly meeting of the shareholders of the Liverpool Overhead Railway Company was held at the Law Association Rooms Liverpool, on Tuesday, Sir W. B. Forwood presiding.

The CHAIRMAN, in proposing the adoption of the report, which appeared in our issue of the 2nd inst., said:—From this report you will see that the gross earnings for the six months amounted to £18,518. 4s. 7d., to which must be added £3,293 balance brought forward, making the total available sum £21,811. 11s. 2d. Deducting from this working expenses for the half-year £13,732. 11s. 2d., interest on debentures, and also interest on calls paid in advance, we have left over the sum of £5,452 available for dividend. Out of this your Directors propose, subject to your approval, to pay a dividend at the rate of 5 per cent. on the Preference shares, and at the rate of 1 per cent. on the Ordinary shares, which will leave a balance of £2,598 7s. 1d. to be carried forward to the next half-year. Your Directors are well satisfied under all the circumstances with the result, for during the greater part of the half-year the trade of the port was most depressed, and the dock omnibuses obtained a considerable measure of support. The total number of passengers carried reached 2,475,639, or roundly at the rate of five millions per annum. The dock omnibuses have probably carried at the rate of 2,500,000 per annum, so that we have a total traffic of about 7,500,000 against 2,300,000, the number carried by the dock busses before the railway was opened. Thus during the first year of the railway's existence the dock traffic has increased threefold, which in itself is a most encouraging feature. Every day the regularity and convenience of this Overhead Railway forced itself more and more upon the public attention and public support. You will notice that during the half-year we have run 46,429 trains, and of these 93·35 per cent. have been on time—a record for punctuality, I believe, never before obtained in the railway world. In comparing the details of revenue and expenditure with the particulars for the preceding half-year, it may appear at first sight that we have spent more money during the past half-year. This arises from the fact that during a considerable portion of the first half we only ran a 10 minutes' service, and therefore our locomotive expenses were lighter and we had no charge for general maintenance and depreciation of machinery, which in our second half absorbed £1,730 9s. 10d. Making these corrections the cost of working comes out precisely the same in both half-years. You will, however, notice that it is over 72 per cent. of our receipts, which looks large as compared with the experience on ordinary English railways, but this test is a fallacious one. If our fares were equal to those charged on ordinary English railways our income would be very much larger, and the ratio of expenses greatly reduced. A better test is to compare our cost of working with the South London electrical railway. Our cost works out 1s. ½d. per mile, and the South London 1s. ¾d. per mile. We hope still to make further economies, and I may mention in this connection that we have taken over the generating station, and that our saving during the first month amounted to £150. The extension to Seaforth will be opened in March, and we have contracted for the erection of three new stations, one near the Nelson Dock, one at the foot of Sandhills-road, and the other at the end of Langton-street, leading to the northern dock system. These stations will be a great public convenience, and will, we hope, give considerable traffic. And now, gentlemen, I have told you my story. I do not intend to enter into the realm of prophecy, for we have a shareholder for whom I have the highest possible respect, who not only treasures up all your chairman's prophetic utterances, but has an inconvenient habit of asking him to live up to them. A chairman of an omnibus railway has many difficult things to encounter, but still, gentlemen, I have never wavered in my opinion that we have a good property. Mechanically it has been a great success, and financially it will also be a success. All we want is a little patience and more faith in our undertaking. It is one of which we may all feel proud, and which is to-day doing a great work in facilitating the trade of the port.

Mr. R. HOBSON, in seconding, expressed his sanguine feelings in regard to the future of the railway. He felt very strongly that it would be a success, but they must give them a little time.

The CHAIRMAN having replied to questions put by shareholders respecting station accommodation, the report was then adopted.

The CHAIRMAN then proposed the payment of dividends at the rate of 5 per cent. per annum on Preference shares, and 1 per cent. per annum on Ordinary shares, less income tax, and that the balance on the net revenue account be carried forward. He hoped that this resolution was the forerunner of many of a still more gratifying character.

Digitized by Google

Mr. G. H. ROBERTSON seconded the motion, which was carried.

The re-election of Mr. James Barrow and Mr. Richard Hobson, the retiring Directors, and of Mr. George Nicholson, the auditor, having been carried,

A vote of thanks was accorded the Chairman, and the proceedings terminated.

Cuba Submarine Telegraph Company (Limited).

The forty-fifth ordinary general meeting of the Cuba Submarine Telegraph Company (Limited) was held at the Company's Offices, No. 58, Old Broad-street, on Wednesday last, Mr. Thomas Greenwood presiding.

The SECRETARY (Mr. James Scott) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, the Directors are pleased to meet you to-day, and to be able to present so satisfactory a report for your consideration. The depression in trade, which has so materially affected a large number of our industrial undertakings, has had some little influence on the receipts of our Company. In comparing the traffic receipts for the past half-year with those of the corresponding half of 1892, there appears to be a reduction £1,122, which has arisen entirely from the exigencies of the trade, not in any sense from a reduction of rates, which has not yet been made. The interest on our investments is rather larger, for during the time that the Australian banks were rearranging their affairs we were without the interest on the money deposited with them, and during the past half-year we have received some arrears which have brought down the sum of increase by £335, so that our net receipts for the half-year were only £787 less than those in the corresponding period of the previous year. Turning to the other side of the account, the London office charges are a little less this year, because there were travelling expenses to Madrid in the corresponding period of the previous year, which were not incurred last half-year. Our outlay at stations has been slightly increased, and I suppose this is likely to continue to do so, because there is always a gradually-improving scale of remuneration paid to the officers and clerks of the Company in consideration of their long and faithful service. Almost all our agreements with our staff have been made on the principle of being increased in ratio to the length of time they are in the employment of the Company. We have also a larger increase in the charge for depreciation on stores and cable in stock. Altogether we have a difference of £470 of expenditure in comparing this half-year with the corresponding half of the preceding twelve months. But this half-year we have had no cable repairs, the consequence being that we have been able to reserve £1,500 against any loss from the deposits with banks and to carry £5,000 to the reserve fund, bringing it up to the large sum of £105,000. I am not quite sure that that policy would have been pursued by the Board but for the fact that we shall find it necessary soon to lay another cable. As intimated to you in the report, the cable which was laid in 1870 between Batabano and Cienfuegos has given out, although we have been using it almost up to the present time, but it has shown lately some indications of further depreciations, and although it has not ceased to speak altogether, its efficiency has been so much reduced that it will probably soon refuse to speak at all. It may recover itself, as it has done before, and in that case we shall continue to use it as long as we can, but it is hardly safe to trust to it, and consequently, we think, that it is desirable to lay another cable between these two points. Under these circumstances the reserve is highly necessary and proper. Perhaps the shareholders would like to know what the ages of our cables really are, since nothing has been said upon the subject in our printed reports. Our cables extend from a distance of about 600 miles in round figures. The portion between Santiago and Cienfuegos represents about 400 miles, and the section between Cienfuegos and Batabano represents about 200 miles. In 1870 cables were laid over both sections, but the section of 400 miles was abandoned in 1881, and the section of 200 miles is the one to which I have referred as being defective in insulation, and will probably have to be abandoned. We have, over the 400 miles, two working cables, one having been laid in 1875 and the other in 1881. We have also, one good working cable laid three years ago over the 200 miles section, and it is over it that we shall soon have to lay another. These are the whole of the items worthy of being brought under your notice, and I will therefore move the first resolution:—

"That the report and accounts for the half-year ended December 31st last, now submitted be received and adopted."

Mr. CHARLES W. PARISH seconded the resolution.

Mr. M. CURRY asked what would be the cost of laying the new cable?

The CHAIRMAN replied that it would be impossible to give the exact figure until the contract was absolutely made. But on referring to the past accounts it would be found that they had laid a cable over the same distance for about £25,000.

The resolution was carried unanimously.

The CHAIRMAN next moved—

"That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income tax, on the Preference shares, and 8 per cent. per annum, free of income tax, on the Ordinary shares, payable on and after to-morrow."

Mr. GEORGE KEITH seconded the resolution, which was agreed to *nem. con.*

The Rev. J. W. BROWN then proposed a vote of thanks to the Chairman and Directors, which was seconded by Mr. S. T. WENTWORTH, and cordially passed.

The CHAIRMAN expressed his acknowledgment, remarking that it would be no fault of the Board if the dividend in the future were not as good as it has been in the past.

The proceedings then ended.

Oriental Telephone and Electric Company (Limited).

The Directors of this Company give notice that an extraordinary general meeting is to be held on Wednesday next, the 21st inst., at the Cannon-street Hotel, E.C., at one o'clock, for the purpose of considering and passing the following resolutions. The Directors point out that it has been their desire for some time past to effect the amalgamation of the two classes of the shares in the Company, so that only one class might exist, and that to be dividend-bearing and free from liability. Since the recent decision in the House of Lords, which was adverse to the interests of holders of Vendors' shares, negotiations have again been opened with the largest holders of these shares in the Company, resulting in a Committee of the Board of Directors meeting these shareholders, and, after protracted sittings, agreeing to the resolutions, which will be submitted to the meeting. Under the new arrangements the Company undertakes to pay all costs of the recent litigation. Arrears due on the Ordinary shares of the Company are to be cancelled, and the Ordinary shareholders will be relieved from all liability as to calls, and the Vendors' shares will come in for immediate dividend, there being only one class of shares of £1 each fully-paid. Ordinary shareholders are to receive one fully-paid share for every two shares held of 11s. paid, and the holders of fully-paid shares will receive 18 for every 20 now held, and the holders of Vendors' shares 15½ for every 20 shares now held.

1. That for the purposes of the reconstruction, hereinafter mentioned this Company be wound up voluntarily, and that Henry Grewing, Esq., and George Bland Frost, Esq., be and they are hereby appointed liquidators for the purposes of such winding up.

2. That, pursuant to Section 161 of the Companies Act, 1862, the liquidators be and they are hereby authorised and directed to transfer to a new Company all and singular the undertaking, property, assets, and effects of this Company, not including uncalled capitall, upon the following terms, with such modifications and additions, if any, as the liquidators may consider expedient:—

(*a*) The new Company shall be incorporated under the Companies Acts, 1862 to 1890, with the name of the Oriental Telephone and Electric Company (Limited), and with a nominal capital of £200,000, divided into 200,000 shares of £1 each.

(*b*) The Memorandum and Articles of Association of the new Company shall contain the same provisions as the Memorandum and Articles of Association of the old Company, subject to such modifications as may be desirable to give effect to the scheme of arrangement the subject of these resolutions.

(*c*) The consideration for the said transfer may be satisfied by the allotment to the liquidators, or as they may direct, of 171,497 fully-paid shares of the new Company.

(*d*) The new Company shall take over and discharge all the debts and liabilities of this Company, and perform all contracts and engagements now binding on it, and shall indemnify this Company and the liquidators against the same.

(*e*) The new Company shall pay (*a*) all the costs of the plaintiffs and defendants of the action Ness *v.* Addison (1891, N. 515), and of the appeals to the Court of Appeal and House of Lords so far as they have not already been paid by this Company; (*b*) the costs of all parties of and incidental to the subsequent negotiations relating to this scheme; and (*c*) the costs of and incidental to the winding up of this Company, and the carrying the said scheme into effect. All such costs to be paid as between solicitor and client.

3. That the liquidators be and they are hereby authorised to enter into such agreements with the new Company or a trustee for the new Company for the purpose of carrying the scheme into effect as they may consider expedient.

4. That the said 171,497 fully-paid shares in the new Company be distributed among the members of this Company as follows, that is to say:—

(*a*) That 58,125 of the said fully-paid shares of the new Company be distributed among the holders of the 75,000 Vendors' shares in this Company, numbered 1 to 75,000, rateably in proportion to the Vendors' shares held by them respectively, being in the proportion of 15½ shares in the new Company for every 20 Vendors' shares in this Company.

(*b*) That 3,372 of the said fully-paid shares of the new Company be given to the holder of the 3,746 fully-paid shares issued by this Company other than those numbered 1 to 75,000.

(*c*) That the remaining 110,000 fully-paid shares of the new Company be distributed among the holders of the 220,000 hsares of this Company upon which 11s. have been called up rateably in proportion to the number of such shares held by them respectively, being in the proportion of one fully-paid share in the new Company for every two shares in this Company upon which 11s. per share have been paid.

(*d*) As regards fractional parts of shares the liquidators may sell any shares which cannot conveniently be divided and divide the proceeds among the persons entitled thereto, and generally may make such arrangements in relation thereto, as they consider expedient.

Should the above resolutions be passed by the necessary majority, they will be submitted for confirmation to a subsequent meeting, of which notice will be given in due course.

Chelsea Electricity Supply Company, Limited.

The following report, for the year ended December 31st last, is issued by the Directors of this company, and will be presented to the shareholders at the meeting to be held at the Central Station, Draycott Place, Chelsea, S.W., on Tuesday next, at 12 o'clock:—

The net profits of the year on the ordinary business of the Company, after payment of interest on debentures, amount to £4,004. 4s. 6d. This sum, together with the balance from the sale of the South Kensington district,

Digitized by Google

gives a net balance of £6,605. 2s. 7d. To meet the wishes of the Board of Trade, the sum of £4,674. 3s. has been deducted from the item of "preliminary expenses" in capital account, and transferred to a suspense account, which account it has been decided to reduce by writing off £2,500. A further sum of £1,000 has been placed to renewals and depreciation fund account, leaving a balance of £3,105. 2s. 7d. available for distribution. The Directors recommend the payment of a dividend on the Ordinary shares of five per cent. for the year, and that the balance of £619. 4s. 3d. be carried forward to next account.

In the month of May last, the purchase of the works, machinery and mains of the Cadogan Electric Light Company was concluded. The generating station, situated in Manor-street, Cheyne-walk, is of sufficient dimensions to contain plant to meet a large increase in the demand. Extensive improvements and additions are in progress at this station.

During the year about 20,000 yards of new conductors have been laid. The increase in the number of lamps connected to the service during the year is 10,665; and, deducting the number of lamps transferred with the South Kensington district, the total number on the Company's mains on December 31, 1893, was 40,665.

The transfer of the South Kensington District, authorised at the extraordinary general meetings held last year, was completed in June.

The satisfactory reduction made in the last few years in the working cost is shown in the following statement of the cost per Board of Trade unit sold:—

Year.	Coal.	Stores and water.	Wages.	Maintenance.	Rent, rates and taxes.	Management.	Renewals and depreciation fund.	Total.	Capital expenditure.	Board of Trade units sold.
	d.	d.	d.	d.	d.	d.	d.	d.	£	
1891......	2·22	0·74	1·11	0·93	0·21	1·56	—	6·77	74,721	290,458
1892......	1·63	0·59	0·95	0·71	0·21	1·26	0·67	6·02	81,364	357,162
1893......	1·11	0·35	0·80	0·53	0·48	1·17	0·59	5·03	99,483	402,848

The retiring Directors are Mr. J. Irving Courtenay and Mr. Nugent Daniell, who, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also offer themselves for re-election.

Westminster Electric Supply Corporation (Limited).

The following is the Directors' report to be presented to the meeting to be held at the offices, Eccleston-place, Eccleston-street, Belgravia, London, S.W., on Wednesday, the 21st inst., at 11 a.m.:—

The Board of Directors, in presenting their report and the accounts for the year 1893, are pleased to state that the business of the Corporation continues to make steady and satisfactory progress.

The Directors have again thought it desirable to reduce the price of current, from 7d. to 6d. per unit, and this change came into effect on April 1st last.

The supply of current which on December 31, 1892, was being provided for an equivalent of 98,686 lamps of 8 c.p., had increased by December 31, 1893, to the equivalent of 131,565, and at the present time there are on circuit the equivalent of 134,268 lamps of 8 c.p., and applications have been received for a further 9,451.

The length of roadway along which mains have been laid now exceeds 35 miles, making about 140 miles of ways, into which upwards of 106 miles of copper (strip and cable) have been drawn.

The plant and machinery have been working satisfactorily throughout the year, and have been fully maintained from revenue. In the manufacture and distribution of electricity, and in the general expenses, a considerable reduction has been effected in the cost per unit.

Since the last meeting, owing to the rapid increase in the Corporation's business, the Directors found it necessary to issue the balance of £30,000 Four and a-Half per Cent. Mortgage Debentures. The issue having been largely over-subscribed by the shareholders, the Directors regretted they were unable to allot in full.

The net revenue of the year amounts to £12,830, out of which £4,370 in payment of an interim dividend at the rate of 3 per cent. per annum for the half-year ending June 30, 1893, has already been distributed. The accounts now show a balance of £8,460 to the credit of net revenue, from which the Board recommend the payment of a dividend at the rate of 5 per cent. per annum for the half-year ending December 31st last, carrying forward a sum of £1,190.

In accordance with the Articles of Association two of the Directors, Lord Suffield and Mr. Hayes Fisher retire, but, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers, also retire.

City of London Electric Lighting Company (Limited).

The following report of the Directors of this Company is to be presented to the shareholders at the ordinary general meeting to be held at Winchester House, E.C., on Thursday, the 22nd inst., at 2:30 p.m.:—

Capital.—The expenditure on capital account during the year ended December 31, 1893, amounted to £260,757. 18s. 1d. Details of this further outlay are given in the Capital Account No. III., the whole of which is rapidly becoming revenue-earning. During the year the remainder of the Preference shares have been issued, and all are now fully paid up. An official quotation for the second issue of £200,000 has been applied for and will no doubt be shortly granted. In order to provide for the additional expenditure which will be necessary to complete the undertaking, the Directors propose to issue debenture stock from time to time, as required. A first issue to the extent of £100,000 will be made immediately, and applications received from holders of the Ordinary and Preference shares of the Company will be preferentially considered.

Revenue.—The gross revenue for the year was		£38,556 10 3
From which must be deducted the following items charged against revenue:—		
Expenses of generation and distribution...	£18,374 14 8	
Repairs and maintenance of plant, machinery, mains, lamp-posts, &c.	2,285 18 4	
	20,660 13 0	
Rents, rates, taxes, and general charges were	2,431 0 8	
		23,091 13 8
Leaving a net revenue of.......................		£15,464 16 7
To which must be added other receipts		1,475 18 3
" " " balance brought forward from 1892		434 6 7
Making a total of		£17,375 1 5

Of this sum £5,333. 6s. 8d. was distributed in July last in payment of an interim dividend on the first issue of £200,000 Preference shares at the rate of 6 per cent. per annum for the half-year ended June 30, 1893, and the Directors recommend a further dividend of 6s. per share on the first issue of £200,000 and of 3s. per share on the second issue of £200,000 Preference shares, both payments being at the rate of 6 per cent. per annum for the half-year ended December 31, 1893. This will absorb £9,000, leaving a balance of £3,041. 14s. 9d., which the Directors propose to carry forward to next account.

After careful consideration the Directors have decided to establish two depreciation reserve funds, the first (Nos. 1 and 1A in the accounts) for the plant and running machinery, engines, boilers, dynamos, &c., and the second (No. 2 in the accounts) for the mains, meters, transformers, and other items from Nos. 2 to 10 in the capital account. For this purpose, out of the premium of £40,000 received from the second issue of Preference shares, £30,000 has been set aside for the first fund, and £9,152. 19s. 3d. for the second.

Owing to the delay on the part of the Local Authority in giving its consent, as required by the Telegraph Act, 1892, to the use of certain tubes for telephonic purposes, the further steps necessary could not be proceeded with, and therefore it has not been possible to include in the accounts the sums payable by the New Telephone Company (Limited) under the agreement. Negotiations are, however, still proceeding, and it is hoped that the consent of the Local Authority will shortly be given.

The working expenses for the year, including repairs and renewals, were 54·2 per cent of the earnings. In view of the exceptionally fine and bright weather, which adversely affected the receipts, and the prolonged coal strike, which seriously increased the expenses, the Directors consider this result satisfactory.

The revenue shows a steady increase, the estimated rate at which it is now being earned being £64,000 per annum gross. This, it is hoped, will be largely increased as soon as the remaining transformer stations are at work.

The Directors were successful in obtaining an Act of Parliament amalgamating the three City districts into one for the purposes of the accounts, and for defining in a clearer manner certain other matters in connection with the Company's Provisional Orders.

Lands and Buildings.—The greater portion of the main buildings is now practically finished, and the remainder is expected to be completed in March next. The pumping station, switch-rooms, and engineers' offices are also in a forward state. Twenty-two transformer stations have been constructed, of which eight are in operation, and every effort is being made to have all the others ready for work during the current half-year. These twenty-two stations when fully equipped will be equal to supplying at least 400,000 8-c.p. lamps installed.

Generating Plant.—The plant already in position is of a capacity of 100,000 8-c.p. lamps, and further machinery is in course of construction by the contractors. The arc-lighting plant has worked satisfactorily throughout the year. The total number of units sold was 1,741,099.

Street Work.—This work is now approaching completion. On February 1, 1894, 580 miles of "ways" had been laid in the City in 55½ miles of streets, into which 105 miles of cables have been drawn. Sufficient "ways" have been laid down to supply a demand of 400,000 8-c.p. lamps installed. Conduits have been laid in all the compulsory streets in the Southwark district.

Private Lighting.—Nearly 1,300 private consumers, representing a total of 72,000 8-c.p. lamps, are being supplied with current from eight transformer stations, and during the current half-year it is expected that the whole twenty-two stations required for the entire City will be at work. Applications continue to come in satisfactorily, the total received to date being equal to the supply of current for 100,000 8-c.p. lamps.

Public Lighting.—The lighting of the main thoroughfares of the City with arc lamps was virtually completed early last year, only a few lamps, for which positions have not been assigned, remaining to be fixed, but the Commissioners of Sewers have not yet given the order for the lighting of the lesser streets with glowlamps. The Company is prepared to carry out the lighting of these streets immediately upon receipt of the order to proceed, the necessary plant for this purpose being already in position. Two of the Directors, Sir David L. Salomons, Bart., and the Hon. Alan Charteris retire, and Sir David L. Salomons, being eligible, offers himself for re-election, but Mr. Charteris, owing to continued ill-health, resigns his seat. The Directors do not recommend that any steps be taken at present to fill the vacancy thus created. Messrs. W. H. Pannell and Co. (the auditors) retire, and, being eligible, offer themselves for re-election

Charing Cross and Strand Electricity Supply Corporation (Limited).

The following is the report of the Directors, to be presented at the annual ordinary general meeting to be held at the Town Hall, St. Martin's-in-the-Fields, Charing Cross, W.C., on Tuesday next, the 20th inst., at 2 p.m. :—

The Directors have to announce to the shareholders with very great regret the death of their Chairman, the late Mr. Spencer Chadwick. Mr. George H. Brougham Glasier, the Deputy Chairman, has been chosen to fill the office of Chairman, and Mr. Richard Chadwick (brother of the late Mr. Spencer Chadwick) has been elected a Director until the Ordinary General Meeting.

The Corporation was on December 31, 1893, supplying energy to 34,570 eight candle-power lamps, an increase of 17½ per cent. on the number supplied at the end of the year 1892.

With the mains added during the past year there are now upwards of 19¼ miles laid.

Two actions were brought against the Corporation for injunctions and damages, both of which resulted in judgments in favour of the Corporation on all points with costs.

The Directors have given special attention to the question of maintenance, renewals and repairs, and have expended a considerable sum in keeping the station in all respects in a very high state of efficiency ; they have also written £200 off preliminary expenses, made provision for bad debts ; carried £700 to depreciation account, £200 to reserve fund, and carried forward £43. 0s. 1d.

The net earnings during the past year have amounted to £8,654. 8s. 4d.; £2,675. 8s. 5d. has been paid in respect of interest on debentures up to December 31, 1893, and £3,648. 7s. 11d. was distributed in payment of an interim dividend for the half-year ended June 30, 1893. A sum of £2,955 10s. 1d. now remains, which the Directors propose to deal with as follows : To payment of a dividend of 4½ per cent. for the year 1893 (less tax), £6,560. 17s. 11d. ; interim dividend paid August, 1893, £3,648. 7s. 11d.—£2,912. 10s. ; carried forward £43. 0s. 1d.—£2,955. 10s. 1d.

Mr. Agostino Gatti and Mr. Stefano Gatti, the Managing Directors, are the Directors who retire by rotation, and being eligible, offer themselves for re-election. Mr. Richard Chadwick being eligible also offers himself for re-election as a Director. The auditors, Messrs. O. R. Johnson and Son, also retire and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRISTOL PHOENIX ENGINEERING AND FOUNDRY COMPANY (LIMITED). This Company has been registered, with a capital of £5,000, in 2,000 £7 per cent. cumulative Preference and 3,000 Ordinary shares of £1 each, to carry on business as mechanical engineers, boiler and tank makers and repairers, iron and brass founders, &c.

JAMES EDWIN ROSS (LIMITED).—This Company has been registered, with a capital of £1,000, in £1 shares, to carry on business as Engineers, manufacturers of patent fuel economisers, iron and brass founders, machinists, &c.

YORKSHIRE STEAM VALVE COMPANY.—Registered as an unlimited Company, with £40,000 capital, issued as paid up, to carry on business as manufacturers of and dealers in valves for steam, hydraulic, gas, and other purposes, mechanical engineers, machine and engineering tool makers, and manufacturers of boilers and boiler mountings, engine fittings and valves, &c.

GENERAL ELECTROLYTIC PARENT COMPANY (LIMITED).—The statutory return of this Company, made up to November 28th, has been filed. Out of a nominal capital of £24,000, in £1 shares, 22,507 have been taken up, and 18,000 issued as fully-paid. Upon the remaining 4,507 shares a call of 13s. 4d. per share has been made, resulting in the payment of £1,500, and leaving £1,504. 13s. 4d. in arrears.

LEEDS AND LONDON ELECTRICAL ENGINEERING COMPANY (LIMITED). The annual return of this Company, made up to November 27th, was recently filed. The capital is £100,000, divided into 250 Founders', 9,750 Preference, and 10,000 Ordinary shares of £5 each. 250 Founders', 734 Preference, and 5 Ordinary have been taken up, and the full amount called on the Founders', 634 Preference, and the 5 Ordinary shares, while a call of £1 per share has been made upon the 100 other Preference Shares. The calls paid amount to £4,545.

LITHANODE AND GENERAL ELECTRIC COMPANY (LIMITED).—The first annual return of this Company, made up to January 3rd, was recently filed. Out of a nominal capital of £100,000, in £1 shares, 20,642 have been taken up, and 17,720 of these have been issued, with 16s. per share considered as paid. Upon these shares a call of 4s. per share has been made, and the full amount has been called on the remaining 3,917 shares. The calls paid amount to £6,286. 17s., leaving £175. 3s. in arrears.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to December 6th, has been filed. The nominal capital is £15,000, divided into 14,950 Ordinary and 50 Founders' shares of £1 each. All the Founders' and 5,855 Ordinary shares have been taken up, and 851 Ordinary issued as fully paid. The full amount has been called and paid on the Founders' and the remaining 5,004 Ordinary shares, resulting in the payment of £4,766. 15s. (which includes a sum of £11. 15s. paid on two Founders' and 116 Ordinary shares which have been forfeited), leaving £299 in arrears.

MULHOLLAND, MAUGHAM AND COMPANY (LIMITED).—The annual return of this Company, made up to December 28th, was recently filed. The nominal capital is £5,000, divided into 120 Founders' and 380 Ordinary shares of £10 each. All the Founders' and 177 Ordinary have been taken and the full amount called on the former, while a call of £5 per share has been made on the latter, resulting in a total payment of £2,085.

NORTH-EASTERN TELEPHONE COMPANY (LIMITED).—The statutory return of this Company, made up to November 13th, has been filed. The nominal capital is £1,000, divided into 500 Preference and 500 Ordinary shares of £1 each. 15 Preference and 452 Ordinary shares have been taken up, and the latter issued with 14s. per share considered as paid. Upon the Preference shares a call of 5s. per share has been made, and upon 28 Ordinary shares, 6s. per share has been called. The calls paid amount to £12. 3s.

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—When the annual return of this Company was filed on December 30th, the whole nominal capital of £100,000, in £10 shares, had been taken up and paid in full.

CITY NOTES, &c.

BABCOCK AND WILCOX (LIMITED).—The Directors have declared an interim dividend for the six months ended December 31st, at the rate of 6 per cent. per annum on the Preference, and 10 per cent. per annum on the Ordinary shares, payable on February 16th.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY (LIMITED).—As announced in our last issue, it is the intention of this Company to invite fresh capital, to enable it to carry out the extension of its tramway system to Kingswood, the extension to be worked by electricity. At the meeting of shareholders held at Bristol last week the proposal was carried unanimously.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Notice is given that the transfer books will be closed, both for Debenture stock and Preference and Ordinary shares, from February 20th to March 5th inclusive.

CENTRAL LONDON RAILWAY.—A special general meeting of the above Company was held on Friday at the offices, 30, St. Swithin's-lane, for the purpose of submitting to the proprietors a proposed Bill, entitled "A Bill to extend the time for the purchase of lands and for the completion of the Central London Railway and for other purposes." Mr. F. A. Lucas presided, and said that the meeting was purely a formal one for the purpose of submitting a Bill to the proprietors for the extension of the time for the purchase of lands and for other purposes. He concluded by moving the resolution as above. Mr. W. Morris (the solicitor) said that by the first Act of 1891 the construction of the railway was authorised from Shepherd's Bush to Cornhill, with a terminal station at Cornhill. By the second Act, 1892, the terminal station in Cornhill was abandoned, and the construction of a central station appointed in the space opposite the Royal Exchange and the Mansion House, while the extension of the line to Liverpool-street was authorised, and powers given to construct a terminal station under the existing Great Eastern station at Liverpool-street. In consequence of having two Acts, the times for acquiring the lands and completing the works expired at different periods, which was found to be a great inconvenience, because the whole line from Liverpool-street to Shepherd's Bush was now one complete line, and not two sections. There yet remained a considerable time for the acquiring of the lands and the completion of the works, but as a measure of precaution, and, as a matter of convenience, it had been thought desirable to apply to Parliament to extend the respective times, and make the time for the acquiring of the lands and the time for the completion of the works apply to both sections of the undertaking. According to the Bill now under consideration, it was proposed that the time for the purchase of land in respect to the whole undertaking should be extended until 1897, and for the completion of the whole works until 1900. In consequence of a paragraph which had appeared in one of the newspapers a little while ago, he wished to state that there was nothing whatever in the Bill to alter the mode of traction intended to be adopted on the railway. The only traction power alluded to was electricity, and it was intended to adhere to that. The resolution was seconded by Mr. H. Smith, and carried.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended February 11th, were £937, as against £952 for the corresponding period of last year, being a decrease of £15. The total receipts for the half-year amount to £5,727, as against £5,862 for the corresponding period of 1893, a decrease of £135.

GAS LIGHT AND COKE COMPANY.—At the 164th half-yearly meeting of this Company, held on Friday last week, Col. W. T. Makins, who presided, pointed out that they had suffered from a considerable diminution in their receipts, owing to the reduced quantity of gas consumed, and that many would, no doubt, assume that the spread of the electric light had brought about this decreased consumption. He, however, thought otherwise, as, in the district south of the Thames served by the Company, where there was little or no electric light, the reduced consumption had been at the same ratio as on other parts of the Company's system, and that this would indicate that, as a competitor, the electric light was not likely to do them serious harm.

GREAT NORTHERN TELEGRAPH COMPANY.—The coupons falling due on March 1, 1894, on the Debentures of 1883 (Series B) should be presented for payment between the hours of 11 and 2, at the office of Messrs. C. J. Hambro and Son, 70, Old Broad-street, where lists may be obtained. Coupons must be left three clear days for examination.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—Traffic receipts for the month of December, £1,488 ; January receipts, £1,682.

NORTH STAFFORDSHIRE RAILWAY.—At the meeting of the Company held in London last week, Mr. T. Salt, the Chairman, stated that by the

Digitized by Google

introduction of the electric light at Stoke station they would be enabled to carry on their work of loading and unloading at night, which would prove a good advantage in the carrying on of the Company's work. The work had been carried out by their own staff, and was giving every satisfaction.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ending February 9th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,007.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 823.—Vol. XXXII. FRIDAY, FEBRUARY 23, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

After several more or less private meetings, one of which formed the subject of two "Notes" in these columns three weeks ago, the triangular duel between electric traction, telephones, and miscellaneous vested interests, opened on Wednesday last. Some thirty-five members were present, and Sir Courtenay Boyle, assisted by Major Cardew, Sir Thomas Blomefield, and Mr. Hopwood, plunged into the Draft Regulations and the observations made upon them by the different bodies. These observations, printed in a slightly different arrangement, to save space, will be found elsewhere in our present issue. The sitting was adjourned after the much-discussed Regulation 14 had been dealt with. We withhold our report of the proceedings and comments thereon until next week, when we shall be able to deal with the whole of this important conference. Meanwhile, we would remark that, so far, all has gone very well, and the edge of No. 14 was taken off by the voluntary suggestion from the Board of Trade to insert after "shall" the words "take all reasonable precautions to."

Careful inspection of manhole boxes is, at present, the only sure preventive of explosions. The onus of making such inspection, as well as the responsibility for explosions, should they occur, might be thrown on the real culprits, the gas companies, who ought to be thankful for the opportunity thus afforded them for obtaining warning of the escape and waste of their wares. It is the practice of the Notting Hill Company to send a man round to all the manholes on the higher parts of their district, where gas would naturally tend to accumulate, to lift the covers, and to search for gas by smelling. It seems a pity to break the joints of the cover so often, and were it not that these explosions, though apparently alarming, seem to be fraught with but little danger, the safety of the inhabitants might be endangered if the soil were of a deodorizing nature or if the official tester caught a cold. But even this mode of testing is a great advance upon no testing at all, and no accident has occurred in this district.

To give a more sure test, an instrument might easily be constructed to measure the percentage of hydrogen present in the manhole, and this without lifting the cover. Fire-damp and gas indicators have been made by taking advantage of the high rate of diffusion of light gases through porous partitions. A thin tube of unglazed earthenware might be mounted at the end of a staff, and be connected with a gauge, the readings being indicated on a dial by means of an aneroid movement, or by mercury in a thermometer tube. Such an instrument could be graduated to show percentages and the limits of explosive mixtures. If temperature errors were found to be appreciable, two similar tubes should be used, but one rendered non-porous; the tubes should be connected by a glass thermometer tube, and the displacement of a mercury index would measure the amount of hydrogen. A 1in. hole in the manhole cover, closed by a lock-flap or screw-plug, would suffice for the test.

The conclusion to which Mr. Schultz has been led by his researches on iron in armatures, an account of which he published in a recent Paper in the *Elektrotechnische Zeitschrift*, is not likely to be accepted by the general body of electrical engineers and dynamo builders without further confirmation. Briefly stated, this conclusion amounts to a denial of the utility of insulation between the laminæ of armature iron; and it therefore practically asserts that it is futile to laminate this iron. Mr. Schultz constructed four armatures, two with thin plates of 0·5mm. (19·69 mils), and two with plates 1mm. thick (39·37 mils); in one of each pair the plates were insulated from each other with paper, while in the other there was no such insulation; the external dimensions of the armature core were the same in all; these were revolved in a field, being driven by an electric motor; the power required for each could be measured accurately; the results of the tests and calculations are given in detail, allowances being made for the different cross-sections of the iron. Mr. Schultz then applies Steinmetz's formula for the loss of energy in a cubic centimetre of iron per period, and arrives at the two following curious results: (1) that in armatures with paper insulation between the laminæ the loss is not less than, but may be as much as 20 per cent. greater than in armatures without such insulation, and (2) that the thickness of the plate has a very important effect on the magnetic losses, the eddy-current waste of power being five times greater in the case of the thick than in the thin plates.

What, in the light of these two dicta, we are to understand is meant by "the thickness of the plate" it is not easy to surmise. Take a very thick slab of iron, and the eddy currents, we are told, will be enormous. Slice the slab into a great number of thin sheets, and place them side by side under sufficient pressure to ensure that the adjacent laminæ

Digitized by Google

are not the least insulated from one another, and we shall find—so we are informed—that the eddy current losses will have wonderfully decreased. Lastly, place an innocent sheet of insulating material between each pair of metal sheets, and, wonderful to relate, the eddy current-losses will be found to have increased as much as 20 per cent. It reads like magic!

From the "advanced" prospectus issued to the "trades interested and users of chemicals," it will be seen that the large-scale experiments which have been going on for some time past at Snodland, Kent, under the auspices of the Electrolytic Caustic Soda and Chlorine Trust, are about to have their natural sequel in the formation of a limited liability company, with a capital of £200,000, divided into 26,000 £5 10 per Cent. Preference shares and 14,000 £5 Ordinary shares. For the patent and all other rights of the Vendor concern £70,000 worth of Ordinary shares, and £30,000 in hard cash or Preference shares is to be given, the "users of chemicals" being invited to take up the remainder of the preferential capital.

The electrolytic method of obtaining caustic soda and bleach from a solution of common salt has undoubted theoretic advantages over the offensive and cumbersome processes at present in vogue, and the vendors have certainly done much to overcome those troublesome little defects which have hitherto barred the way to commercial success. By the use of common gas-retort carbon anodes cast in a lead frame, and costing for renewals but a few shillings per ton of caustic soda turned out, the unattackable and unobtainable anode has been given the go-by. The porous and fragile diaphragm, compounded somewhat after the manner of the Macbethian hell-broth, of parchment, asbestos, and coagulated blood albumen, has been done away with. Finally, the employment of a copper cathode covered with a superficial film of copper oxide has brought down the volts per vat from 6 to 4, the theoretical minimum voltage being 2·02.

On the other hand, the huge profits which are predicted by the experts, even if the estimates of the cost of production upon which they rest are sound, depend firstly on the validity of the patents; secondly, on the surpassing excellence of the process; and, thirdly, on the judicious use of the commercial leverage afforded by the ownership of a superior process protected by valid patents. The validity of the patents, it is stated, has been thoroughly well ascertained, and we have independent reasons for believing them to be good ones; but the protection afforded by the thin armour of a patent, especially where "prodigious profits" are concerned, is about as illusory as it is on board a modern ironclad. But assuming that the Holland and Richardson patents are indefeasible, unless the process is beyond comparison the best that human ingenuity can devise, it may be predicted with certainty that human ingenuity, urged thereto by "enlightened self-interest," will not be long in evolving something similar. Again, assuming both patent and process to be unassailable, "prodigious profits" will not be realised unless the present market price of caustic soda and bleach is maintained. If the Electro-Chemical Company and its licensees take to turning out sufficiently large quantities of these chemicals, prices are bound to come down, but the appetite of the manufacturing community for caustic soda and bleach is almost insatiable. The success of the process owned by the Electro-Chemical Company would, however, give an immense impetus to the electrical industry, and on that account we wish it all good fortune.

It is interesting to note that this electrolytic process has been the cause of three careful estimates of the cost of the electrical horse-power hour when the plant is running continuously the year through. Mr. Swinburne, in his Paper on "Problems of Commercial Electrolysis," which was discussed at the Institution of Electrical Engineers in November, 1892, gave the figure ·1875d. Messrs. Cross and Bevan, in a Paper read about the same time before the London Section of the Society of Chemical Industry, gave ·178d. Dr. John Hopkinson, in a recent report to the Electrolytic Caustic Soda and Chlorine Trust, gives ·2461d. In all three cases much the same sized plant is assumed, and coal, labour, stores, and depreciation are included.

Personal.—Mr. Henry D. Wilkinson, M.I.E E., who has lately returned from Chicago, was married, last Tuesday, to Miss Morgan, of Cape Town, at Christ Church, Crouch End, London.

A Disadvantage of Using Water-Power.—In the early part of the winter the electric lighting station at Toulouse had to stop working for a time on account of a fall in the level of the River Garonne.

Royal Society.—The Bakerian lecture, "On the Relations between the Viscosity (internal friction) of Liquids and their Chemical Nature," by Prof. Thorpe and J. W. Rodger, was delivered yesterday.

The "Drehstrom" at Dresden.—It may interest our readers to know that the "drehstrom" plant for the Dresden Railway station has been built, and is now ready for erection on the site. The generating station has already been constructed.

Scientific Teaching.—Lord Playfair has select d "The Modern Needs of Scientific Teaching" as the title of his address to the students of the London Society for the Extension of University Teaching, at the Mansion House, on Saturday, March 10th.

Edison Lamp Decisions.—We have received from the General Electric Company, of New York, a handy file containing the various legal decisions on the Edison filament lamp patents of the United States, Canada, and Great Britain, together with copies of the injunction orders issued by the United States courts up to the present time.

Telegraphy without Wires.—The Paper on "Electric Signalling without Wires," which was read before the Society of Arts last Wednesday by Mr. W. H. Preece, has attracted considerable attention from the daily Press. Our readers will already have been informed as to our views about the experiments which were described in that lecture, for we have several times commented upon them on previous occasions.

Insulation of House-wiring in the City of London.—The City of London Electric Lighting Company gives notice that it is prepared to enter into agreements with consumers to examine their fittings, &c., at stated intervals on payment of an annual fee of 10s. The men who make the test will hand the consumer a signed report specifying the insulation resistance, with a note on the general condition of the wires and fittings at time of inspection.

Electricity Supply of Berlin. A Correction.—In the abstract on p. 417 of our last issue of the report of the Berliner Elektricitätswerke a serious error crept into the figures relating to capital expenditure on land, mains, and plant; these should respectively be £305,000, £340,000, and £190,000, and not

Digitized by Google

as stated. The indebtedness to the Allgemeine Elektricitäts Gesellschaft should have been stated as £358,000, not £35,800. It may be mentioned that the average price obtained in Berlin for the kilowatt-hour is no less than 7·8d.

Nottingham.—Prof. W. Robinson has hardly been doing yeoman's service in the cause of electric lighting in this town, by giving a popular lecture at the University College on the subject of the so-called electric explosions and fires. The lecture was suggested, we understand, by recent occurrences in London, Glasgow, and Manchester electric light conduits, as well as by the fact of the forthcoming introduction of the electric light into Nottingham. We hope that the edification and amusement of the Nottingham people will not deter them from adopting the electric light in their homes and streets.

Electrically-Lighted Lifebuoys.—According to *Industries and Iron*, some trials have just been made at Kiel on board the German war vessel "Wörth" with an electrically-lighted lifebuoy, the invention of Capt. Melter. The buoy was thrown overboard when the vessel was proceeding at a speed of about sixteen knots. For a space of about twelve seconds it was lost in the eddy currents caused by the screws of the vessel, but then reappeared. The new lifebuoy will be found useful at night-time, and the experiments resulted so successfully that it is probable that it will be adopted generally in the German navy.

Dangerous Car Speeds.—The limit of speed for electric train cars in the City of Brooklyn, according to *Engineering*, is fixed by the municipal regulations at 10 miles an hour, which is, of course, a substantial increase on our Board of Trade maximum of eight miles per hour. In spite of this, however, it seems that the 10-mile limit has not been at all strictly observed in Brooklyn, the cars running faster in every part of the town save the most crowded streets. Unlike the cable system, in which the maximum speed is fixed by that at which the engines of the central station are run, the electric system leaves the question of speed very much under the control of the motor man on the car, who can vary it within wide limits. In the steam tramcars in this country it was, and is, the practice to fit a governor, which applies the brakes if the speed exceeds the Board of Trade limit. When, however, this governor was driven by a belt, the engineman not unfrequently removed it, and could thus run at almost any speed he liked.

Boiler Incrustation.—In his address before the Railway Association of Berlin, Herr Bork observed that petroleum has been, of late, a good deal used in Germany as a means of removing boiler incrustation. The boiler is first cleaned out with hot water and allowed to dry; and then the deposit is sprayed with petroleum, which it absorbs. The boiler is then filled with water and the work is gone on with in the ordinary way. Before the boiler has been long at work it is found that the scale has chipped and crumbled off, and loosened so much that there is no difficulty at the next cleaning in getting it completely removed. It is as if vapour of petroleum had been formed in the interstices of the scale, and as if this had blown the scale to pieces, by minute expansions here and there. Of course, care must be taken not to bring a lamp flame too near the boiler after spraying the scale with petroleum. There are, however, some particularly hard and compact scales in which the above treatment has no effect; they absorb no petroleum, and they can, accordingly, not be broken up by it.

Wire Thieves.—For some time, says the *Western Electrician*, the Chicago Telephone Company has been troubled by the loss of wire. Frequently as much as six or seven miles had been removed from one place. The operations of the thieves were not confined to overhead wires, but service wires in conduits were also stolen, and it is said that fully forty miles of telephone wire have been lost by the Company in the last three months. A month or so after the telephone Company began to suffer, the South Side electric railways also began to lose wire. Once or twice every week a raid would be made on one of the electric lines, and an aggravating delay would follow until the break could be repaired. The loss of the companies soon ran into hundreds of dollars on traffic alone. One fine Sunday afternoon two young men were seen winding up half-a-mile of wire on Lake-street. They were arrested, and it is thought that the leaders of a gang engaged in this work have been secured. Other arrests have been made, and it is to be hoped that the telephone and railway companies will now be allowed to give uninterrupted service.

Electrical Communication with Lighthouses.—In the estimates recently submitted to Congress there is an item of $50,000 for establishing electrical communication between lightships and the shore. A note accompanying the estimates states:—"The House of Representatives Committee on International and Foreign Commerce on 6th December, 1892, asked the views of the Treasury Department as to the Bill appropriating $50,000 to provide communication from light ships and outlying lighthouses to the shore. Favourable reply was made on December 8, 1892. Since then the Lighthouse Board has experimented, and is now satisfied that it can establish electrical communication between lightships and the shore. It is proposed to commence with an important lightship quite near shore, then take a more important one more distant, and then, if need be, another still further away, and thus acquire by successive effort the experience needed to successfully lay an electric cable to connect with the shore the most distant and important lightship, that on the New South Shoals, some thirty miles off Nantucket, Mass."

Bi-Metallic Telephone Conductors.—Concerning bi-metallic telephone wires, says Mr. A. E. Kennelly, in the *Electrical Engineer* of New York, it appears that any proposition which asserts that a combination of two metals in a conductor is superior for telephonic purposes to a similar conductor of either metal alone, seems to be entirely new, deserves to be considered with circumspection, and lays the burden of proof entirely upon experimental evidence. In the case of iron, however, it is orthodox to suppose that the inductance possessed by an iron wire is advantageous in long distance telephony within reasonable limits if the resistance of the conductor were at the same time capable of being sufficiently reduced. Also that when a definite adjustment between inductance, resistance, and capacity of the conductor has been attained, it is consistent with present recognised views to suppose that a comparatively low insulation can be permitted. In this connection lies the possibility for a superiority of a compound iron-copper wire over one wholly of copper or of iron, but even then the advantage, if due to these reasons, should attend definite relations of composition and disposition in the wires and not iron-copper wires indiscriminately.

The Pacific Cable.—Under date February 18th, the Ottawa correspondent of *The Times* states that it has been definitely decided that the Intercolonial Conference to consider matters relating to the Australian trade and to the proposed Pacific cable shall meet at Ottawa on Thursday, June 21st. The Imperial Government, all the Australasian colonies, and Fiji will be invited to send representatives; and it is probable that Hawaii will also be asked to take part. The Canadian Government, it is stated, are not wedded to any particular route for the cable. They only stipulate that it shall begin and end on British territory, and that it shall be under British control. At a meeting of the London Chamber of Commerce last week, a Paper, entitled "Reciprocal Trade with Australia," was read by the Hon. Robert Reid (Victorian Minister of Defence). In the course of the discussion that followed, Lieut.-Gen. Sir Andrew Clarke said he intended to ask the London Chamber of Commerce to help him in approaching the Government on the subject of establishing communication between Canada and Australia by means of a cable line and a fast line of steamships in the Pacific. That would give England an alternative route, and would be a source of immense strength to her.

The Electricity of Drops.—At a meeting of the Cambridge Philosophical Society, on January 27th last, a Paper on "Electricity of Drops" was read by Prof. J. J. Thomson. The experiments and observations of Lenard were first referred to. No electrification is detected in a free falling drop, but if drops after falling be arrested by coming in collision with a plate or wire, the droplets generated in the splash are found to be electrified. The electrification of a free falling drop is masked by the opposite electrification of the air surrounding it, till by some sudden blow the drop is broken up. Special observations show that the blow does not generate the electricity, but merely separates already existing opposite electrifications. The effects produced by various liquids have been studied, and it appears that there is an obvious connection between the nature (reducing or oxidising) of the liquid used and the kind or amount of electrification detected. A very small amount of impurity in water is enough to produce a marked change in the electrification observed. The most remarkable case is that of phenol; this substance is only moderately soluble in water, but if only 0·2cc. of water saturated with phenol is added to 100cc. of pure water, the increase in electrification is obvious; and when 2·5cc. of solution are added to 100cc. of water, the effect on the electrometer is nearly seven times that due to pure water. The sign and magnitude of the electrification depend on the nature of the gas through which the drops fall before breaking up, hydrogen producing effects opposite to those produced by air. No electrification can be detected when drops of water fall through pure water-vapour, but the smallest addition of air brings about electrification.

Large Electric Power Transmission in Norway.—The large number of unused waterfalls in Norway is, says our Scandinavian Correspondent, attracting more and more attention, since the electric transmission of power has come to the fore, and there is every reason to believe that several large installations of this kind will ere long be realised. The latest and one of the most sensible plans of this kind refers to the transmission to Christiania of some 20,000 H.P. from two waterfalls, the distance of which from the capital is in both cases less than 25 miles. Although there is an available water power of 20,000 H.P., it is only proposed to convey 10,000 H.P. for the present. The current will be transmitted at a pressure not exceeding 20,000 volts, and the idea is to use bare wire. The lines will be railed in the whole of their length, and watchmen will be placed at every three miles, and where the lines pass through forests a belt 33ft. in breadth will be cleared, and altogether every conceivable precaution will be taken. On the outskirts of Christiania a distributing station will be placed, which will be common to both lines; the pressure will there be reduced, and the current will be distributed to the various parts of the town by means of underground cables, at a pressure of 100 to 400 volts. It is proposed to apply this considerable power to a number of varied purposes: power will be supplied to the different industrial establishments, both large and small; it is also proposed to use it both for tramways, local railways, and local steamers; further, the syndicate is prepared to light the town, either the whole of it, or only the part which is outside the area of the already existing central station. An application for the necessary concession has already been made, and the authority of Lord Kelvin's name is mentioned in support of the scheme, which is well thought of, and it is considered possible to complete it before the end of 1895. The estimated cost is about £300,000.

Institution of Civil Engineers: The Education of Students. The main idea of the amended regulations as to the education of engineering students, issued by the Council of the Institution of Civil Engineers is, we are told, "to make the regulations more consistent in themselves, and to allow an elasticity formerly wanting, without lowering the standard of general education previously demanded." The hope is expressed that no corporate member will receive as a pupil, or as an apprentice, any one failing to possess the limited qualifications required by these regulations. The following are the new regulations:—(1) No person will be admitted as a student unless he produces evidence of a competent knowledge of the subjects specified in the following list:—(1) English, comprising Grammar, Composition, History and Geography. (2) The elements of Mathematics, comprising (*a*) Arithmetic, including Vulgar and Decimal Fractions, (*b*) Algebra, including Quadratic Equations with one unknown quantity, (*c*) Geometry, including the fi st three books of Euclid *or* Trigonometry, including the solution of plane triangles. (3) Two of the following subjects, not more than one of which shall be a language:—(*a*) Latin, (*b*) Greek, (*c*) French, (*d*) German, (*e*) Italian, (*f*), Spanish, (*g*) Elementary Mechanics of Solids Fluids, (*h*) Elementary Geology, (*k*) Elementary Physics, (*l*) Geometrical Drawing, (*m*) Elementary Heat, (*n*) Elementary Electricity and Magnetism. (2) The evidence required in the above regulation shall be furnished by certificates to show either—(A) That the candidate has obtained any one of the educational distinctions, or has passed one of the qualifying examinations included in Schedule No. I.; or (B) That the candidate has passed examinations in the qualifying subjects, by one or more of the recognised Public Examining Bodies contained in Schedule No. II. (3) The Council may from time to time extend, alter, or otherwise amend the Schedules Nos. I. and II. (4) The Council reserve to themselves power to accept special qualifications of practical work in lieu of certain educational qualifications; or to waive any of the above-named requirements under special circumstances as they may think advisable.

Solidified Petroleum as a Fuel.—The high thermal value and cheapness of petroleum, and the inconvenience of burning it in furnaces in the fluid state, have led to many attempts to solidify it. The method of making fuel bricks of crude petroleum, adopted by Signor Maestracci, of the Italian Navy, is given as follows by the *Revue Scientifique*:—The bricks are of similar form and size to the coal briquettes extensively used in France and Germany. The mixture is made in the proportion of 1¾ pints of petroleum, 10 per cent. of rosin, 5¼oz. of powdered soap, and 11½oz. of caustic soda. The mixture is heated and stirred at the same time; solidification begins in about ten minutes, and the operation must then be carefully watched. If there is a tendency to remain liquid a little more soda is added. The mixture is stirred until the mass becomes nearly solid. The thick paste is then poured into the moulds, which are placed for 10 or 15 minutes in a drying stove. The briquettes are then cooled, and are ready for use in a few hours. Signor Maestracci recommends the addition of 20 per cent. of wood sawdust, and 20 per cent. of clay or sand, which will make the briquettes cheaper and more solid. In trials made at Marseilles on several tug-boats the petroleum briquettes furnished about three times as much heat as coal briquettes of the same size. They were burned in the ordinary boiler furnace, without any special preparation, and gave out very little smoke, leaving also little or no ash. The advantages claimed for the petroleum briquettes are the absence of smoke and a large reduction in bulk of fuel which must be carried, as compared with coal, while the risks attending the carrying of liquid fuel are avoided. The question as to whether it is more economical to burn petroleum than coal turns entirely on the relative cost of the two fuels, coupled with the comparison of their respective evaporative values. For the purpose of firing steam boilers the use of the higher qualities of petroleum, such as that used for illuminating purposes, is altogether out of the question on the score of price, as the process of rectification to which the crude petroleum is subjected very much enhances the cost. One of the simplest methods of burning the crude oils in steam boilers is that adopted by Messrs. Nobel at their well-known oil works at Baku. It consists of a series of shallow trough burners, arranged in a series one above the other, thus exposing a large surface. As the oil trickles down it flows from one stage to the other, and is thus vaporised and completely consumed by the time it reaches the lower tier of troughs. With this system of trough burners, it is stated, a practical evaporation of 14½lb. of water per pound of petroleum refuse has been obtained, as compared with an evaporation of 7lb. to 8lb. of water per pound of coal under similar conditions. The more common and practical method of burning these oils, however, is to spray them into the furnace tube or combustion chamber with a jet of superheated steam by an injector, which draws in the air supply at the same time.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 88.*)

Advantages and Disadvantages of Alternate Currents.

The special points in favour of the alternate-current systems may be summarised as follows :—

(*a*) High-pressure machines are permissible, since the currents are not commutated, and, therefore, sparking difficulties are entirely obviated.

(*b*) Power is readily divided into units of any size and at any pressure, by suitable transformers—either step-up or step-down.

(*c*) The regulation of pressure over a large area of supply is facilitated by parallel high-pressure primary circuits.

(*d*) The power in any of the branch circuits can be regulated by choking coils without serious loss—thus the pressure of a feeder, or the light of a single lamp, can be graduated without using a wasteful resistance.

(*e*) Alternate currents are generally more easily handled than continuous currents, and the sparks at breaking circuit are less virulent.

(*f*) Synchronous motors of large sizes have a high all-round efficiency, and necessarily run at constant speed.

(*g*) Asynchronous motors can be made without collecting rings and brushes, and are of very simple construction.

(*h*) Separately driven alternators will run perfectly in parallel if the self-induction of the armatures be of suitable amount —too much or too little self induction lowers the plant efficiency, renders the condition unstable, and the load will not be proportionately divided between the several machines.

(*i*) Two alternators of unequal pressure may be coupled in parallel, and will give an intermediate pressure.

The chief drawbacks to alternate currents are :—

(1) Transformers, especially small ones, are not efficient with low load factors, and therefore transformer substations are advisable.

(2) Synchronous motors are not self-starting, and will stop if temporarily overloaded.

(3) Asynchronous motors will not start against the designed average torque, and are only efficient at high loads.

(4) The lag between current and pressure in an inductive circuit, such as one loaded with motors, is productive of wasteful current in the copper circuits. This is specially the case when the total useful power is small.

(5) Synchronous alternators are more costly to build than dynamos of equal output.

(6) Alternate-current transformers fed with the primaries in series at constant current require the secondary circuits to be also fed with constant current.

(7) Free-running synchronous alternate-current motors will not work in series.

(8) Alternate currents are not suitable for electrolytic purposes.

(9) There is some difficulty in regulating the pressure of supply in circuits containing induction and capacity.

In these sections only single-phase currents are considered, and hence the term alternate current will be limited here to this meaning.

Series Working not possible: Single Alternator and Motor.

It was shown in a previous portion of this series that the simplest case of transmission of power with continuous current is that in which one dynamo and one motor are run in series with each other. The same is the case with alternate currents ; but series working is strictly limited to two free-running synchronous machines. Properly speaking series working is impossible with synchronous machines. A reversed alternator runs perfectly as a motor when driven off a similar generator if it run in synchronism with it. The term synchronism usually implies that the periodic time of the alternations of the two machines is the same, and not that they are co-phasedly equal. Theoretically, it is sufficient that the frequency of one machine either coincide with, or be equal to a small multiple of that of the other, but in practice only the first case has been hitherto realised.

* All rights of reproduction reserved.

It has been already shown that the frequency is equal to the number of pairs of poles in the field-magnets multiplied by the number of revolutions of the armature (or field-magnets) per second. Therefore, if the machines be similar the speeds must be the same when synchronism obtains ; and if the numbers of poles in the two machines differ, the revolutions will vary inversely as the relative numbers of poles. From these considerations it is seen that a synchronous alternate-current motor is *not self-starting ;* and that the moving part must be started and revolved until it falls into step with the generator. This is most readily accomplished by running the generator slowly until the motor has got into step with it when the speed of the dynamo may be gradually increased, and the motor speed will follow it with considerable persistence. This will be comprehended by reference to the following diagram.

In Fig. 83 let V be the curve of pressure of the alternator running as a generator ; *v*, the curve of counter pressure of a similar machine running as a motor, and assume that by means of suitable adjustment of both field-magnet excitations, V is greater than *v* by an amount sufficient to drive the current *i* through the combined circuit. Then the work given out by the generator at any instant is equal to the product of the corresponding ordinates of V and *i*, as N L × M L ; and the work absorbed by the motor at the same instant is – L N_1 × M L. The sign is taken as positive when either of the curves is above the time line and negative when below it. The total work done by either machine in one complete cycle can be obtained graphically by dividing the time line into any number of equal parts, when,

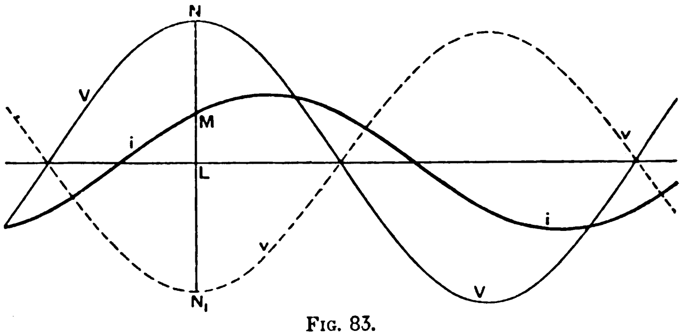

Fig. 83.

if the time of one-half period be equal to T, then the several values of $V\,i\,\frac{T}{n}$ and $v\,i\,\frac{T}{n}$ can be readily found and plotted in new curves whose areas will be proportional to the respective outputs. Care must be taken to use the right signs, and to recollect that the algebraic product of two negative quantities is reckoned as positive ; hence the values of V *i* in the second half of the generator curves are positive, although each of the factors are negative. The negative sign before the product V *i* implies that the machine is *receiving power* from the circuit, whilst the contrary shows that the machine is *giving power* into the circuit. The displacement of the current curve, *i*, with reference to the resultant pressure V – *v*, is called the lag. The amount of the lag is usually measured in degrees and is determined by the self-induction of the circuit.

Parallel Working with Alternate Currents.

Alternate-current working is seen at its best when the alternators as well as the transformers are coupled in parallel. The term "parallel working," indeed, is usually held to imply this particular arrangement of the generators, and does not refer to the transformers, although these are generally coupled in parallel as well. The ordinary practice is to drive each alternator separately. In Continental practice two alternators are frequently coupled, one at each end of a turbine shaft, the whole forming one unit. Machines of unequal size work perfectly in parallel, dividing the load in proportion to their capacities, if the excitations be properly adjusted and the armatures have a suitable amount of self-induction. And alternators of even widely different pressures may be coupled parallel without risk of damaging either, the resultant omnibus pressure being intermediate between the two. But the load

will not be necessarily divided according to the capacities of the two; and the machine with the higher internal pressure will do work on that with the lower pressure during a portion of each period. Therefore, the power absorbed will be greater than is necessary, and may be excessive. In fact, the difficulty with parallel working is to proportion the load according to the several capacities of the generators. It is necessary to measure, by means of a *wattmeter*, the power given out by each machine, and to adjust the excitation and the steam admission until the load is properly distributed. An ammeter is of no use, since it gives no indication of the lag between the current and pressure, and, of course, the omnibus pressure is necessarily the same for all the machines. As previously mentioned, the engines (or turbines) should not have separate governors, but the throttle valve of each should be first properly adjusted, and then fixed. The main supply of steam (or water) being controlled by a single governor, affecting all the prime motors. Further adjustment of output must be made by the field excitation, the safest condition of working being given, not by the minimum current, but by pushing the excitation beyond the lowest point of the volt-ampere curve, so that a slight rise of speed will increase the *armature* current, and the converse will bring it to its normal value. This is technically known as giving the alternator "backbone," and permits of small variations of speed without sensibly altering the omnibus pressure.

Alternate currents are adapted for—

(*a*) Simple parallel and reverse parallel systems, either direct or with transformers.

(*b*) Two-wire feeder systems, direct or with transformers; and

(*c*) Multiple-wire feeder systems, direct or with regulators or transformers.

It is in the transformer systems that they compare most favourably with direct currents, for dynamotors cannot seriously compete with transformers either in prime cost, efficiency, or durability. It is important to examine carefully the use of transformers, since they are likely to play a leading part in all large power plants in the future.

It is sufficiently clear that high pressure is essential in the transmission mains from economical considerations; and it is also evident that the distributing pressure must not exceed about 500 volts. It has already been shown how these two conflicting conditions are met in continuous-current working by means of regulators, dynamotors, and other devices, all, however, having moving parts, and, therefore, requiring attention more or less continuously, being always liable to breakdowns from mechanical defects, and subject, also, to wear and tear from mechanical friction. It would be unfair to the continuous-current systems to lay too much stress on these points, but they undoubtedly must weigh heavily in the judgment of engineers when comparing these two great classes of electric machinery.

In alternate-current working the connecting link between the feeders and the distributors is the transformer. Reference has already been made to the structural details and to the fundamental features of design. It remains to investigate the functions of the transformer, and to see how admirably it meets the many and varied requirements of power and lighting work. It was shown that the construction is of the simplest character involving no moving parts, and comprising merely a laminated iron core and two separate windings of copper wire, the cable being protected by an iron case commonly filled with resinous oil. From the engineering point of view, it is as near perfection as possible, a machine of the highest efficiency without moving parts, and requiring no attention. If properly designed for the work expected of it, there is no reason why it should not last for an indefinite period without repairs of any kind.

In parallel working, the transformers may be banked at sub-stations, and any number may be coupled up to the distributors according as the load varies, the necessary connections being made by an attendant on the spot; or the switching may be controlled by magnetic devices worked automatically or from the central station. The load factor of each transformer must be kept as high as possible, though the load factor of the station may vary largely. To attain this end it is necessary to select the transformer unit so that the minimum load is about 75 per cent. of the maximum output of one transformer. As soon as the full load of one transformer is reached, a second is switched in. With this arrangement no transformer will run with a load factor of less than 50 per cent., at which the efficiency is about 95 per cent. If the maximum load obtains for only short periods it may be advisable to have some larger transformers in addition to the small ones, but this is a matter of detail which must be settled on the merits of each case.

Another method, which was largely practised in the early days of alternate-current working (and is still now in commencing a new plant), is to place a transformer in the premises of each consumer. It has several disadvantages. In the first place, the prime cost of small transformers is necessarily more per unit of output than that of large ones; and secondly, the size of the transformer must be chosen with reference to the maximum, and not to the average, load; and hence the all-day load-factor will of necessity be small in most cases, often in lighting plants not averaging more than 10 per cent. When this system is carried out on a large scale for lighting, the result is disastrous as regards coal consumption, which may reach as high as from 20lb. to 25lb. of coal per kilowatt-hour at the terminals of the lamps (one Board of Trade unit delivered). Whereas the best continuous-current three-wire systems consume from 6lb. to 8lb., and sub-station alternate-current plants not more than from 10lb. to 15lb. This disparity is due to the efficiency of transformers being comparatively small at low loads, and also because the exciting currents must be supplied whether the secondary circuits are closed or open. Hence the primary circuits carry large idle currents, which are wasted in heating them and the transformers. The power thus lost has been variously estimated at from 10 to 15 per cent. of the total station power. This difficulty, however, is not likely to be so serious in the case of power work, for with large motors the load-factor will generally be high, and the transformers can always be switched out of circuit when the motors are standing, lamps (if used) being supplied from a separate transformer. And in the case of a number of small motors, such as a manufacturing town or a large factory, a transformer sub-station can be easily arranged to deal with both light and power work.

(*To be continued.*)

THE NEW TELEGRAPH CABLE IN THE ST. GOTTHARD TUNNEL.

The first telegraph cable in the St. Gotthard Tunnel was laid in the year 1882 by the firm of Felten and Guilleaume, of Mulheim-on-Rhine, and although supplemented by a three-core telegraph cable and a concentric telephone cable only a couple of years ago, soon afterwards the installation was found inadequate to cope with the rapidly increasing demands upon it, so that the Swiss telegraph authorities decided to lay yet another cable, and this was accordingly done in September and October, 1893.

The peculiarities of this tunnel telegraph line made it inevitable that in laying the first cable many unexpected difficulties would present themselves and have to be overcome, thus the greatest care had to be exercised by the manufacturers in only employing materials offering the greatest resistance to the chemical influences to which the cables are exposed in the tunnel. It must be borne in mind that even the iron superstructure of the railway has suffered from the water and fumes in the tunnel, the water containing sulphuretted hydrogen and sulphides and the fumes carbonic acid, sulphurous acid, and ammonia. The uncommonly high temperature of the tunnel (73°F. at times) also influences the choice of material.

A special feature was the provision of an effective sheathing for the cable, the danger of mechanical injury being very great. This is explained by the fact that work of some kind or another is almost continually going on in the tunnel, and what with the darkness, the high temperature, the impurities in the atmosphere, and other circumstances, it is extremely difficult to prevent mechanical injury to the cable. The presence of sharp stones in the tunnel of itself made a good sheathing imperative.
